CHEMICAL & METALLURGICAL ENGINEERING

Weekly Technical Newspaper, Being the Incorporation of Electrochemical and Metallurgical Industry and Iron and Steel Magazine

McGraw-Hill Company, Inc., New York City

Volume XXVII

From July 1 to December 31, 1922

GENERAL ALPHABETICAL INDEX

PAGES

July 5 ..... 1 to 48
July 12 ..... 49 to 96
July 19 ..... 97 to 144
July 26 ..... 145 to 192
Aug. 2 ..... 193 to 240
Aug. 9 ..... 241 to 288
Aug. 16 ..... 289 to 336
Aug. 23 ..... 337 to 384
Aug. 30 ..... 385 to 480
Sept. 6 ..... 481 to 528
Sept. 13 ..... 529 to 576
Sept. 20 ..... 577 to 624
Sept. 27 ..... 625 to 672
Oct. 4 ..... 673 to 722
Oct. 11 ..... 723 to 770
Oct. 18 ..... 771 to 816
Oct. 25 ..... 817 to 862
Nov. 1 ..... 863 to 910
Nov. 8 ..... 911 to 960
Nov. 15 ..... 961 to 1008
Nov. 22 ..... 1009 to 1056
Nov. 29 ..... 1057 to 1104
Dec. 6 ..... 1105 to 1152
Dec. 13 ..... 1153 to 1200
Dec. 20 ..... 1201 to 1248
Dec. 27 ..... 1249 to 1286

A

Aberdeen ordnance test program 660
Abrasive, Corundum, artificial (P.) 273
Absorption:
——Increasing rate of (P.) 993
——Rate of flow affects (N.) 1210
——Tower (N.) 1210
——Properties of zeolite 1211
Abstracts, Engineering 10
Accelerated reactions in pulsating gaseous currents. Deschamps and Shadgen 1269
Accidents in mills and smelters in 1921 .. 937
Accounting—See also Cost Accounting
——And factory efficiency. Comer 417
——Chemical plant. Wadsworth 101
——Needs of technical men. Thornton .. 925

ACETONE:
——Market review 476
——Solvent for bitumens, asphalts and oils 651
——Solvent for mineral and rosin oils .. 751
——Solvent for nitro cellulose (B. P.) .. 994
——Solvent for varnish-gums, resins, etc. 693

ACETALDEHYDE:
——From acetylene (P.) 895, 1185
——Paraldehyde and metaldehyde equilibria. Danneel 216
——Process for formaldehyde (B. P.) 130
——Reaction rates 370
Acetylene:
——Mfr. acetaldehyde from (P.) 1185
——Products. Mfr. (P.) 895
——Purifying (B. P.) 755, 1186
——Recovery from other gaseous hydrocarbons (P.) 895

ACID:
——Acetic anhydride mfr. (P.) 1089
——Acetic, market review 476
——And phosphate data wanted 805
——Carboys, closure problem 1267
——Concentration:
—— Cascade system (N.) 11
—— Dilute nitric. Carpenter and Babor 121
——Corrosion of Cr steels. Rawdon and Krynitsky 171
——Corrosion report 1072
——Fatty, Esters of (B. P.) 1138
——Hydrochloric:
—— Direct from H and Cl (N.) 12
—— New absorber (N.) 12
—— New vessel for absorption. Tyler .. 223
—— Comment. Laury. Tyler 340
—— Tyler 774
—— Tank cars (N.) 12
——Manufacture. Neglected ingredient. Zeisberg 457
——Mixed:
—— Distillation of. Zeisberg 1025
—— Production statistics 1002

ACID—Nitric:
—— Air bleaching of. Whitman and Evans 686
—— Bleaching (N.) 12
—— Distillation and concentration. Zeisberg 1025
—— Iron free (P.) 1232
—— Market review 476
——Oxalic. Tariff rate 1091
——Phosphoric:
—— Electric furnace production. Comment. Carothers 149
—— For fertilizer (P.) 225
—— Furnace method (N.) 13
——Picric for state roads 713
——Production statistics 1002
——Resistant material. Solubility of quartz packing (N.) 11
——Spent oxide used in British plants .. 197
——Sulphuric, See Sulphuric Acid.
——Tannic, plant for Fiji Island 663
——Tartaric
—— In Italy 198
—— Italian manufacturers merge 608
Aczol—an interesting wood preservative .. 509
Adhesives from starch (B. P.) 179
Adhesives research 1095
Adsorption a criterion of corrosion. Saklatwalla 647
Administrative efficiency, Measuring. Polakov 404
Advisory committee of War Department .. 1140
Aeronautics, Developments to be A.S.M.E. topic 949
Africa, Fertilizer industry in South 108
Agriculture:
——Chemists to meet 712, 1000
——Chemists meet 1047, 1092
——Farmers using picric acid 568

AIR:
——Compressed, as aid to production efficiency 412
——Conditioning:
—— And personal efficiency 449
—— At exposition 642
—— Importance in factories 1078
——Ionized for preventing static discharge. Jones 942
——Reduction Co. to manufacture in Birmingham 183
——Reduction Co.'s profits 282
Alby Co. collapse 931

ALCOHOL:
——A.C.S. committee secures government support 135
——Attempt to adopt uniform standard .. 229
——Dehydrating (B. P.) 1138
——Denatured. Doran 345
——Denaturing provisions 1278
——Dephlegmating column (B. P.) 179
——Dialkyl sulphates from (B. P.) 561
——Distillery in Canada 998
——For chemical engineer. Doran 345
——From ethylene (B. P.) 612
——From methane (N.) 594
——From Trent amalgams. Davis 1087
——Government regulation of (N.) 636
——Marketing and distribution problems. Tunison 471
——Motor fuel in England 726
——Ruling protested 1091
——Statistics for 1922 1280
——Tariff debate 613
——Varnish industry petitions for 1044
——Wheeler exposition address 629
A'dehyde, Butyric, mfr. (P.) 322
Alien property disposal would be investigated 38
Alkali market from jobbers' viewpoints. George 473
Alkali phosphates (B. P.) 1186
Allied Chemical and Dye active 282

ALLOYS:
——Aluminum 501
—— Bronze for French coins 893
—— Cu-Si tests (N.) 15
—— For casting 501
—— High strength (P.) 1042
—— Improving by aging 510

ALLOYS—*Continued:*
—— Mg 502
—— Molding practice 555
—— Si, Properties and mfr. Edwards .. 654
—— Zn 501
——Bearing. Tests on high-tin, Priestley. 928
—— Comment. Holz 106
——Brittleness of tinfoil (S.) 610
——Copper, Influence of iron (S.) 992
——Electrical properties at high temperatures (N.) 680
——Experimental furnace for 1085
——Ferro:
—— Beclouded by tariff. Bradin 472
—— Duty based on buyers' analysis 950
—— Electric furnace for. (S.) 1232
——Ferrosilicon, Corrosion of (N.) 595
——"Modification" of Al:Si. Curran ... 360
——No. 31 502
——Overstrain, internal stresses and creep. Jeffries and Archer 833
——Pure Fe:C:Mn 170
——Steel:
—— Endurance tests of 366
—— For airplane shafts. Kothny 1020
—— Forgings, Hair cracks in 803
—— High-silicon sheets (P.) 611
—— Importance of (S.) 992
—— Plant for Canada 35
—— Plants merge 762
—— Rapid sorting (S.) 992
——Titanium, ... 1012
——Vacuum fused, of electrolytic iron with C and Mn (N.) 677
——White metal. A.S.T.M. standard (N.) 15

ALPHA CHI SIGMA:
——Exposition dinner 615
——Members will register at exposition. 327
——Plans dinner 517
——To banquet 278
——To reorganize alumni 182
Alum in tanning (P.) 945
Alumina:
——From clay, Miguet process (S.) 848
——Mfr. (B. P.) 755
——From impure ore (P.) 611
——Zirconia crucibles for steel analysis .. 638

ALUMINUM:
——Alloys:
—— For casting 501
—— High strength (P.) 1042
—— Improvement by aging 510
—— Polishing for metallographic study. Dix 1217
——Bronze:
—— Effect of iron (S.) 992
—— Etching 264
—— For French coins 893
——Bauxite deposits in Tennessee 564
——Chloride, mfr. (B. P.) 561
—— Method of cracking petroleum distillates (P.) 1041
——Coating on iron and steel (P.) 610
——Electrolysis with barium (B. P.) 612
——Furnace, Melting losses in, Correction 6
——Industry in Switzerland 177
——Mechanical properties, Effect of temperature etc. Jeffries and Archer. 747
——Melting in electric furnace (N.) 681
——From leucite (B. P.) 614
——Physical tests (N.) 14
——Plating (P.) 610
——Polishing for metallographic study. Dix 417
——Products in 1921 764
——Protective coatings for 649
——Silicon alloys, "Modification" of. Curran 360
——Silicon alloys, Properties and mfr. Edwards 654
——Tariff rates 375
Al Uminum. You know me 652
American Association for Advancement of Science program 1240

AMERICAN CERAMIC SOCIETY:
——Canadian meeting 486
——Chicago section:
—— Annual meeting program 996
—— Annual meeting 1238

(P), (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

AMERICAN CERAMIC SOCIETY—*Continued:*
——— Danville meeting ... 86
——Exposition program ... 518
——Exposition meeting ... 634
——Joint meeting, Eastern section with clayworkers ... 947
——Plans summer excursion ... 35
——Summer meeting plans ... 227

AMERICAN CHEMICAL SOCIETY:
——Alcohol committee secures government support ... 135
——Chemical Education Section, Pittsburgh ... 583
——Committee denied interview with Harding ... 181
——Committee invites criticism of society policies ... 658
——Co-operates with Petroleum Institute on fuel problems ... 807
——Council announces $25,000 prize ... 567
——Council meeting, Pittsburgh ... 580
——New laboratory at Yale to be dedicated at spring meeting ... 900
——Pittsburgh meeting:
——— Plans ... 88
——— Preliminary program ... 132
——— Meeting:
——— Council meeting ... 580
——— General meetings ... 581
——— Cellulose Section ... 582
——— Chemical Education Section ... 583
——— History of Chemistry Section ... 584
——— Division of Fertilizer Chemistry ... 585
——— Division of Sugar Chemistry ... 586
——— Division of Physical and Inorganic Chemistry ... 586
——— Leather Section ... 588
——— Section of Gas and Fuel Chemistry ... 589, 648
——— Division of Petroleum Chemistry ... 590
——— Division of Industrial and Engineering Chemistry ... 591
——— Rubber Division ... 595
——— Dye Division ... 596
——— Smoker, You know me, Al Uminum ... 652
——— Ohio State chemists at meeting ... 661
——National elections ... 1278
——Planning 1923 meeting ... 88, 1237
——Spring 1923 meeting, Committee chairmen ... 900
——To educate legislators in chemistry ... 808
——Will pass on papers before meeting ... 998

AMERICAN ELECTROCHEMICAL SOCIETY:
——Baltimore electrochemists organize ... 135
——Co-operates with Bureau of Mines on research ... 947
——Electrodeposition symposium (N.) ... 676
——Montreal meeting:
——— Plans ... 374
——— Program ... 515
——— Report ... 676
——Moves to N. Y. ... 35
——New York meeting:
——— Plans ... 374
——— Program ... 1093
——New York section hears of Burma ... 1045
American Engineering Council to meet ... 1140
American Engineering Standards Committee:
——Code for conveyors ... 36
——Conference on numbering steel ... 1046
——Numbering of steels referred to ... 1235
——Significance of standardization ... 447
American Foundrymen's Association:
——Directors organize ... 997
——Will co-operate with French ... 997
American Gas Association, Atlantic City meeting ... 920

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS:
——Dinner plans ... 276
——Dinner ... 614
——Election ... 1204
——Headquarters at exposition ... 565
——Niagara Falls meeting ... 8
——Oppose licensing ... 1236
——Report of dinner ... 614
——Richmond meeting:
——— Program ... 1043
——— Meeting ... 1204
——To banquet during exposition ... 519
——To establish student chapters ... 760
——To survey college courses ... 759
American Institute of Mining and Metallurgical Engineers:
——Plans for Frisco meeting ... 182
American Iron and Steel Institute:
——Alloy steel production figures (S.) ... 992
——New York program ... 760
——Semi-annual meeting, N. Y. ... 867
American Metric Association meeting plans ... 1279
American Mining Congress
——To organize southern division ... 567
American Peat Society meeting ... 324
American Petroleum Institute:
——Co-operates with A.C.S. on fuels ... 807
——Meets ... 1190
American Railway Association standardization work ... 448

AMERICAN SOCIETY OF MECHANICAL ENGINEERS:
——Committee chairmen ... 949
——Convention report ... 1188
——Management week ... 853
——Plans engineering museum ... 327
——Plans N. Y. meeting ... 949
——Symposium on waste-heat boilers ... 267
——To meet at power show ... 850
American Society for Testing Materials:
——Atlantic City (June) meeting ... 14
——Committee work on conductivity of refractories. Hull ... 538
——Discussion on failure of paint and varnish on exposure (N.) ... 551
——Nitrate explosives. Cavalier ... 692

AMERICAN SOCIETY FOR STEEL TREATING:
——Classes in heat-treating ... 1000
——Detroit meeting:
——— Plans ... 372
——— Program ... 567
——— Meeting ... 727
Amines, aromatic (B. P.) ... 1187

AMMONIA:
——Canadian plant to resume operation ... 1278
——Oxidation (N.) ... 12
——— By catalysis. (P.) ... 1137
——— Process (B. P.) ... 755
——— Work of Sheffield Experiment Station. Curtis ... 699
——Soda process (P.) ... 993
——Stills (N.) ... 157
——Synthetic. Mfr. N and H for (N.) ... 12
——— Drying N and H (P.) ... 1274
——Synthesis, summary of work on ... 1235
Ammonium
——Sulphate mfr. (B. P.) ... 756
——Sulphate, Market review ... 477

ANALYSIS:
——Commercial lime. Holmes and Fink ... 348
——N in iron and steel (S.) ... 944
——Of coal, Study of (S.) ... 757
——Of metals for gas. Simons ... 248
——Of refined lead. French ... 219
Aniline, Market review ... 479
Annatto industry in Latin America. Wilson ... 600
Anodophoresis, definition. Ralston ... 778
Anthraquinone mfr. (B. P.) ... 179
Antimony
——Effect on bearing metal. Priestley ... 928
——Industry of Hunan, China ... 1024
Appleby bill, Will support ... 374
Ardeer, Visit to. Hendrick ... 297

ARSENIC: See also Calcium Arsenate
——Market review ... 477
——Market situation ... 185
——On free list ... 323, 375
——Shortage, Facts and figures on ... 1241
——Situation clarified by conference ... 1234
——Tariff burden discussed ... 229
——Tariff causes Senate flurry ... 183
——To investigate scarcity ... 1141
——Will survey situation ... 1191
Art and science in leather mfr. Seymour-Jones.
I—Flaying, curing, etc. ... 1110
II. Preliminary wetwork ... 1253

ARTIFICIAL SILK:
——Cellulose acetate (B. P.) ... 561
——Developments in Britain ... 726
——Industry, Italian ... 871
——Industry. Schlatter ... 533
——Patents. Schlatter ... 537
——Process (B. P.) ... 561
——Setting bath (B. P.) ... 896
——Spinning solution (B. P.) ... 994, 1274
——Vegetable extract in precipitation bath (B. P.) ... 1090
Asbestos roofing, mfr. Finley ... 800

ASPHALT:
——In waterproofing and in paints. Finley ... 802
——Petroleum, in roofing and waterproofing. Finley ... 798
——Production from petroleum. Finley ... 800
Association of Iron and Steel Electrical Engineers:
——Stansfield to address Cleveland section ... 709
Association of Official Agricultural Chemists:
——Meeting plans ... 712, 1000
——Meeting ... 1047, 1092
Aston wins Nobel prize ... 1142
Atlas dividend ... 521
Atmospheric nitrogen—See Ammonia
Atmospheric pollution
——By SO_2 (N.) ... 11
——Developments in France. Negru ... 1069
——Litigation held in abeyance ... 181
Australian power project ... 713
Australia, Tanning investigations in ... 761
Automatic equipment and chemical control. Montgomery ... 150
Automatic process control symposium A.C.S. (N.) ... 591
Automatic process control (N.) ... 851
Automobile, How much steel in ... 30
Automobile—See Motor Fuel
Automotive industry, steel requirements ... 868

B

Badische plants closed by strike ... 1239
Bake ovens. Comment. Sandstrom ... 1060
Baking capacity of flour. Dunlap ... 174, 934
——Comment. Nasmith ... 1262
Barium:
——Chloride, market review ... 477
——Chloride from black ash waste (P.) ... 1089
——Fused, in Al electrolysis (B. P.) ... 612
Barrel tipping device. Potts ... 78
Barrels:
——Handling sugar. Montgomery ... 779
——Wooden, for chemicals ... 1231
Barytes, tariff rates ... 375
Batteries:
——Dry cells, Electrical characteristics of. Vinal and Ritchie ... 550, 603
——Storage, for locomotives. Todd ... 554
——— Stotrage, Method of determining the rate of sulphation of storage battery plates. Vinal and Riitchie ... 1116
Bauxite:
——New development in Tennessee ... 564
——Titanium from (B. P.) ... 896
Bayer complaint dismissed ... 1047
Bearing metal:
——High-tin. Tests on. Priestley ... 928
——— Comment. Holz ... 1061
Bearing Metal—Continued:
——Tin base, new standard ... 324
Belgian:
——Artificial silk industry ... 746
——Cement makers dominate market ... 998
Belgium, Industrial status. Negru ... 917
Bentonite, Use for de-inking newspaper ... 744
Benzanthrone, derivatives (B. P.) ... 946

Benzene:
——Market review ... 480
Benzoic acid, New standard ... 324
Benzol, poisoning, its occurrence and prevention. Horan ... 605
Benzol denaturant ... 1278
Beryllium, extraction (P.) ... 656
Bessemer medalist (Honda) ... 196
Beta naphthol. Market review ... 480
Birds' preserve doomed ... 661
Bismuth. Effect of, in lead. French ... 219
Bisulphites, Reducing to hyposulphites (B. P.) ... 130
Black ash, $BaCl_2$ from (P.) ... 1089
Black fractures in carbon tool steels. Green ... 265
——Comment:
——— Emmons ... 484
——— Green ... 485
——— Honda ... 484
——— Johnson ... 485
——— Mathews ... 484
——— Schwartz ... 774
Blast furnace practice, Principles of ... 1037
Blast furnace 130 years old ... 999
Blasting, Comminuted smokeless for (S) ... 848

BLEACHING:
——Earths (B. P.) ... 130
——Oil with ozone (N.) ... 850
——Process (B. P.) ... 706
——Powder:
——— Corrosive action of. Young and Peake ... 974
——— Desulphurizing gasoline with, (B. P.) ... 1186
——— For sweetening gasoline. Young and Peake ... 972
——— Market review ... 477
——— Rendering stable (B. P.) ... 656
——— Stabilizing (B. P.) ... 946
——— Tariff discussion ... 616
Blue gas for heating coke oven. O'Malley ... 75
Boiler Plate:
——After cold-work or work at blue-heat. French ... 211
——Effect rate of loading on tensile properties. French ... 309
Boilers:
——Electric (N.) ... 681
——Flue gas testing ... 1070
——Introducing Kestner, in Britain ... 198
——Waste heat ... 267
Boiling point, change in, due to drying. Hendrick ... 544
Boll weevil, Fighting from air ... 567

BOOK REVIEWS:
——33, 34, 80, 81, 82, 83, 128, 129, 178, 319, 368, 369, 511, 512, 559, 560, 610, 707, 756, 894, 933, 1041, 1089, 1139
——Aitchinson. Engineering Steels ... 560
——Batson and Hyde. Mechanical Testing ... 178
——Beilby. Aggregation and Flow of Solids ... 319
——Bingham. Fluidity and Plasticity ... 610
——Brooks. The Chemistry of the Non-Benzenoid Hydrocarbons ... 559
——Brown. The Lead Storage Battery ... 756
——Byers. An Outline of Qualitative Analysis of Inorganic Substances, Including the Rare Elements ... 82
——Chamot. Elementary Chemical Microscopy ... 33
——Church. Manufacturing Costs and Accounts ... 80
——Clay Products Cyclopedia ... 1089
——Cornubert. Dictionnaire Anglais-Francais-Allemand de Mots et Locutions Interessant la Physique et la Chimie ... 894
——Cronshaw. Oil Shales ... 34
——Cross, Roy. Handbook of Petroleum, Asphalt and Natural Gas ... 1183
——Deerr. Cane Sugar ... 81
——Elements of Industrial Heating ... 756
——Falk. Catalytic Action—Catalysis, With Special Reference to Newer Theories of Chemical Action ... 512
——Foerster. Elektrochemie Wasseriger Losungen ... 319
——Gow. The Electrometallurgy of Steel. 895
——Grasser. Synthetic Tannins: Their Synthesis, Industrial Production and Application ... 757
——Guertler. Metallographie ... 320
——Hackspill. L'Azote. La Fixation de l'Azote Atmospherique et son Avenir Industriel ... 1041
——Hall, John Howe. The Steel Foundry 1183
——Hanneman "Hütte." Taschenbuch für Eisenhüttenleute ... 178
——Hart. A Textbook of Chemical Engineering ... 757
——Hendricks' Commercial Register of the United States for Buyers and Sellers 129
——Hofman. Metallurgy of Zinc and Cadmium ... 511
——Holmes, Harry N. Laboratory Manual of Colloid Chemistry ... 1183
——Ibbotson. Analysis of Non-Ferrous Alloys ... 894
——Journal of the Institute of Metals ... 560
——Journal of the Iron and Steel Institute 1139
——Korzybski. The Manhood of Humanity: The Science and Art of Human Engineering ... 80

BOOK REVIEWS—*Continued:*
——Liddell, Donald M. Handbook of Chemical Engineering.
——Loeb. Proteins and the Theory of Colloidal Behavior 368
—— Comment:
—— Alexander 821
—— Wilson 628
——Locke, John F. A Handbook for Electrotypers 1139
——Mellor. A Comprehensive Treatise on Inorganic and Theoretical Chemistry 129
——Methods of the Chemists of the U. S. Steel Corporation for the Sampling and Analysis of Pig Iron..... 1089
——Mills. Within the Atom 129
——Mineral Industry During 1921..... 993
——Norris. The Principles of Organic Chemistry 368
——Osann. Lehrbuch der Eisen-und Stahlgiesserie 1041
——Price and Brown. Dust Explosions.. 511
——Pring. The Electric Furnace..... 83
——Progress of Applied Chemistry..... 34
——Publicity Methods for Engineers.... 512
——Pulsifer. The Determination of Sulphur in Iron and Steel..... 894
——Review of Papers on Electrodeposition and Electroplating 82
——Rogers. Practical Tanning..... 511
——Shreve. Dyes Classified by Intermediates 82
——Taggart. A Manual of Flotation Processes 128
——Thomson. Rays of Positive Electricity and Their Application to Chemical Analyses 707
——Von Richter. Organic Chemistry, or Chemistry of the Carbon Compounds 707
——Wheeler. Entropy as a Tangible Conception 34
——Worden. Technology of Cellulose Esters 657

Books:
——Best on Steel..... 754
——Research bibliography. Comment. Walker 774
——Selected by paint men..... 759
Borax:
——Effect of, in fertilizer (S.)..... 757
——Elimination from American potash. Ross and Hazen 167
Borneol, from pinene (B. P.)..... 130

BRASS:
——De-zincification of (N.)..... 678
——De-zincification of. Comment. Bassett 340
——Effect of heating on elasticity. Jeffries and Archer..... 833
——Influence of iron (S.)..... 992
——Internal stress in. Jeffries and Archer 833
——Tubes, Internal stress in (S.)..... 321
—— Comment. Bassett 340
Brazilwood industry in Latin America. Wilson 600
Bread, Effect of maturing flour. Dunlap 171, 934

BRICK: See also Ceramics.
——Fire, Mfr. of. Wikoff..... 505
——Mfr. at Laclede-Christy Clay Products Co. Wikoff 969
——Refractory (P.) 370
——Refractory, Collect data on 1143
Brinell testing, Balls used for..... 924

BRITISH:
——Adhesives research 1095
——Chemical industries 7, 197, 532, 726, 965, 1109.
——Chemical industry's problems and ours. Hamer 915
——Dye situation 494
——Editor's impressions of U. S. Hamer. 915
——Institute of Metals. Program..... 849
——National Physical Laboratory report. 210
——Prepared for gas..... 807
——Steel industry. Comment. Hodson. 964
B.t.u. chart. Lohman 1031
Brondse process 7

Bronze:
——Aluminum, Etching 264
——For French coins..... 893
Budget as means of industrial control. Rautenstrauch 415
Buffalo University inaugurates Capen... 898
Bureau of Chemistry:
——Appropriation 1101
——Emphasizes achievements 1275

BUREAU OF MINES:
——Announces investigation program.... 87
——Annual report 1189
——Appropriation for non-metals..... 328
——Committee on oxygen in metallurgical operations 943
——Completes fluorspar investigation.... 712
——Concludes clay products study..... 659
——Co-operates with A.E.S. on research.. 947
——Gasoline studies 1118
——Progress in fluorspar investigation.. 135
——Studies U. S. potash plants 1142
——Whiteware studies 649

BUREAU OF STANDARDS:
——Announces new samples and renewals 324
——Annual report 1235
——Apparatus for magnetic analysis of metal 366
——Appropriation 1191
——Bids Stratton farewell..... 1278
——How it holds employees..... 1234
——Loses Stratton 805
——Platinum thefts 372
——The national. McBride 1159

Burma:
——Electrochemists hear of (N.)..... 1045

BUSINESS:
——Conditions:
—— Fundamental 1049
—— Improving 40
——Cycle as factor in production efficiency. Trigg 428
——Cycle. Upward swing of 1144
——Expansion in 1922..... 1280
——Failures, Reasons 1049
——In iron and steel industry (N.).... 867
——Library to be selected 227
——Outlook for better 520
——Present trend and conditions. Person. 1165
——Progress, Clearing way for..... 714
——Promotion 1049
——Revival awaits strike settlement..... 232
——Side of chemical manufacturing:
—— Wadsworth V 101
—— Wadsworth VI 293
——Volume shown by tax receipts..... 712
Butyric aldehyde, Mfr. (P.)..... 322

C

Caetani:
——Appointed Ambassador 996
——To be honored at banquet..... 1048
——To be welcomed..... 1279

CALCIUM:
——Acetate market..... 233
—— Market review..... 477
——Arsenate:
—— Deterioration tests..... 995
—— For boll weevil..... 567
—— Mfr. (P.) 1274
—— Mfr. Ambruster..... 159
—— Correction. Ambruster..... 340
—— Situation clarified by conference.. 1234
——Carbide industry, Collapse of, at Odda 931
——Carbide in Norway..... 832
——Carbide (N.)..... 683
——Chlorate or hypochlorite mfr. (B.P.) 994
——Hypochlorite, Stabilizing (B. P.).... 656
——Silicide as a deoxidizer..... 311
Calculation of theoretical maximum temperatures. Brown..... 497
Calculations, Slide rule for furnaces..... 889
Calibration of tanks (N.)..... 156
Calorific value of coal, Chart for. Lohman 1031
Camphor:
——From pinene (B.P.)..... 139
——Tariff debate 613
——Tariff rates 375

CANADA:
——Cement investigations 660
——Chemical industries..... 1096
——Fish oil factory in 951
——Iron oxide export to U. S. stopped... 376
——New oil discoveries 275
——New paper mill 663
——New petroleum refinery 564
——Oil development in Alberta..... 661
——Oleomargarine, regulations in..... 662
——Paper mill ordered sold 278
——Paper production growing 659
——Paper manufacturers oppose Newfoundland development 662
——Topographical Survey equipped for thermometer standardization 638
——Steel alloy plant for 35
Candelilla wax in Mexico..... 919
Capen inaugurated at Buffalo 898
Capital increases....48, 95, 144, 239, 335, 526, 575, 623, 769, 816, 909, 960, 1008, 1055, 1104, 1151, 1247

CARBIDE:
——Collapse of industry at Odda.....931
——Industry in Norway..... 832

CARBON:
——Activated:
—— As catalyst. Bradley and Parr.... 739
—— At Exposition 639
—— Catalyst for NH_3 oxidation. Curtis. 702
—— For desulphurizing gas (P.) 1137
—— For solvent recovery (P.)..... 322
—— In chlorination of hydrocarbons (P.) 1233
—— Manufacture (B. P.).....130, 179
—— New theory of efficiency (N.).... 586
—— Purifying (P.) 706
——Bisulphide
—— Mfr. of. Richter 838
—— Substitute for, as fumigant 1141
——Black:
—— Efficiency of plants. Bubb..... 4
—— Economic status of (S.)..... 559
—— Factors affecting yield 733
——Combustion apparatus 30
——Dioxide:
—— In food products (N.)..... 631
—— Liquid for carbonating (P.)..... 993
—— Research on 1047
—— Weighing 1070
——Electrical resistivity of 933
——Electrodes, Graphite from (P.)..... 611
——Electrodes. Mantell. See Technology of C electrode industry.

Fine chemical industry dependent on chemist. Pfanstiehl 457

FIRE:
——Extinguisher:
—— Causes panic 133
—— Pyrene safe 328
——Nitrate barge 324
——Plant of Duquesne Steel Co 1093
——Prevention exposition planned 327
Fireclay refractories, Mfr. of. Wikoff .505, 969
Fish oil factory in Canada 951
Fixed Nitrogen Laboratory report 1235

FLOUR:
——Central export facilities for 954
——Chemists, Short course for 661
——Maturing I. Dunlap 174
——Maturing II. Dunlap 934
Flue gas analysis 1072
Fluidity (N.) 805
Fluorspar:
——Bureau of Mines completes investigation 712
——Investigation, Progress in 135
Fly-by-nights, Eliminating in chemical industry. Kutz. 471

FOOD PRODUCTS:
——Artificial milk (B. P.) 561
——Carbon dioxide for air in (N.) 631
——Danish margarine 1921 1040
——Ginger-ale plant of Beech-Nut Packing Co. Montgomery 150, 199
——Human factor in industry. Barbour. 464
——Maturing flour. Dunlap 174, 934
——Oleomargarine mfr. (B. P.) 179
——Oleomargarine in 1922 1281
——Polish industry 1157
——Regulation of butter substitutes in Canada 662
——Starch from wheat flour (B. P.) ... 755
——Vitamine content of canned foods (S.) 559
Foreign trade, Trend 809
Foreman training. Nussbaum 435
——Procedure in 438

FORMALDEHYDE:
——Catalytic production from acetaldehyde (B. P.) 130
——From CO by catalysis (B. P.) 612
——From methane (B. P.) 946
——Market 233
——Market review 477

FRANCE:
——Chemical industry improving in 58
——Conditions in chemical industries. Negru 1068
——Devastated coal regions of. Negru 1013
——Dye situation in 933, 1068
——Electrolytic iron development in 684
——Foundrymen to co-operate in convention in 997
——Honors Dwight and Rand 230
——Hydro-electric development in 804
——International exposition on liquid fuel 565
——Iron ore production in 703
——Monetary status. Negru 966
——To use bronze coins 893
——Unemployment in. Hodson 964
——War explosives in. Cavalier 689
Franklin medal presented 231
Franklin, E. C.:
——Elected A.C.S. president 1278
——Plans lecture tour 662
Fraud alleged in Old Hickory deal 325
Free port provision part of tariff bill 374

FREIGHT:
——Car loading as index of distribution. 185
——Summary of, for 1922 1280
——Cars, R. R. must pay for spotting .. 663
——Car supply asked 762
——Rates:
—— Duty of seller to ship at lowest .. 500
—— On carboys protested 1233
—— On cyanamide 227
—— On fertilizer protested 1093
—— On tank cars protested 1095
—— On heavy chemicals protested 37
——Refund awarded Grasselli 277
——Sulphur, protested 227
Fritz medal given Marconi 87

FUEL:
——Comparison in ceramic industry 1276
——Economy in D. C. 775
——Economy in Illinois 1096
——Industrial, Gas as. Wright 442
——Liquid:
—— In metallurgical furnaces (N.) ... 868
—— International exposition on 565
——May distribute byproduct gas as 1141
——Metaldehyde as. Danneel 216
——Motor.—See also motor.
—— Effect of S in (N.) 590
—— Effective volatility (N.) 590
—— Eliminating knock (N.) 581
—— French work on. Negru 1069
—— Improving economy (N.) 996
—— Process for (B. P.) 562, 1233
—— Quality of (S.) 609
—— Road tests for comparing 1062
——Symposium at Iron and Steel Institute 867

FULLERS EARTH:
——Bleaching activity (B.P.) 130
——Comment, Morris 53
——Decolorizing efficiency (N.) 590
——For filtering vapors (P.) 1232
Fulweiler:
——Wins Grasselli medal 850
Fume:
——Control device (P.) 79
——Litigation held in abeyance 181
——Removal by ventilation. Nichols and Ellis 540
Furfural, Commercial, properties and uses. Miner, Trickey and Brownlee:
—— I. Occurrence, mfr. properties .. 299
—— II. Bibliography 362
——Resins (N.) 595

FURNACE:
——Calculations, Slide rule for 889
——Coal-fired, for patenting wire 1129
——Electric—See also Electric Furnace:
—— Heat insulating materials (N.) .. 681
—— Principles of design (N.) 680
—— Resistivity of resistor carbons (N.) 680
——Heating, for blooms, slabs and billets (N.) 867
——Insulation. Increasing efficiency by. 441
——New for enamel smelting (N.) 1210
——Radiating, at exposition 642
——Regenerator, for powdered coal (P.) 611
——Reverberatory for refining Cu (P.) .. 611
Fusion rotary retort (S.) 1187
Fustic industry in Latin America. Wilson 599

G

Gages, Precision, Steel for 754
Galvanic corrosion on monel yacht:
——Comment, Hough 964
—— Howard 1156
——Reply, McKay 964
Galvanized iron:
——Device for weighing coatings 797
——Rapid Zn test (N.) 15

GAS:
——Absorption, Calculations on (N.) 1210
——Analysis, Basis for automatic control (N.) 851
——And fuel chemistry, A. C. S. section of, Pittsburgh 589, 648
——Association, Atlantic City meeting .. 920
——Blue, for coke ovens 922
——By-product, Removal of tar from. Washburn and Muns 119
——Coal:
—— Alcohol from (B. P.) 612
—— Desulphurizing, (P.) 1137
—— Ethylene derivatives from (B. P.). 561
—— Ferrocyanides from (B. P.) 755
—— Recovery of pyridine (P.) 560
—— Use of steam in retorts 1164
——Coke oven:
—— Ammonium sulphate mfr. (B. P.). 756
—— May distribute as fuel 1141
—— Pyridine. Dehydrating (P.) 1041
——Determination of, in metals. Simons. 248
——Distribution (N.) 920
——Electrical precipitation of solids from. 753
——Explosion prevented by new device Weber 942
——Fired baking furnaces. Mantell 315
——For industrial processes. Wright 442
——Heat standard established 711
——Illuminating, Removal of S from ... 1136
——Industry, growth of (N.) 850
—— Technical situation in. Brown ... 466
——Masks, Industrial (N.) 922
——Meters, Recording (N.) 920
——Natural:
—— Absorption of gasoline from (S.). 609
—— Benzol and toluol from (P.) 993
—— For C black (S.) 559
—— Tables and charts. Anderson 1039
——Pipes and meters, deposits in (N.) .. 921
——Plant construction (N.) 923
——Poison:
—— British prepared for 807
—— Effective for dispelling mobs 1140
—— Officially tabooed by Army 136
—— Peace-time uses (N.) 630
—— Peace-time value. Weeks (N.) 1045
—— Used as fumigant 373
——Producer:
—— Accelerated reactions in by pulsating currents. Deschamps and Shadgen 1269
—— Apparatus (P.) 33, 370
—— For coke ovens (N.) 922
——Producers for glass works (N.) 635
——Pulcating flow of, Accelerated reactions in. Deschamps and Shadgen 1269
——Purification by selective oxidation (P.) 513
——Recovery of cyanides from (P.) 513
——Sales increase 952
——Scrubber (B. P.) 656
——Scrubber (P.) 561
——Water:
—— Doherty cooler as condenser (S.) .. 990
—— For heating coke ovens. O'Malley .. 75
—— Machine combined with retort. (P.) 1138
—— Scrubbing (N.) 921
Gaseous:
——Detonation (N.) 996
——Reactions, Accelerated, in pulsating flow. Deschamps and Shadgen 1269
Gasification of Ohio coals. Demorest.
I. Preliminary survey 1172
II. Results and conclusions 1221

GASOLINE:
——Absorption from natural gas (S.) .. 609
——Comparing by road tests 1062
——Desulphurizing by bleaching powder (B. P.) 1186
——Evaporation loss 924

(P), (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full

GASOLINE—*Continued*:

The Chemical Exposition as An Adjunct to the College Course

TEACHERS of chemical engineering and industrial chemistry will find it worth while to make a special effort to bring their classes to the Chemical Exposition to be held in Grand Central Palace during the week of Sept. 11. As an educational adjunct it is doubtful if the Chemical Exposition can be surpassed, when one considers that in it are gathered together the products of the manufacturing brains of the industry. A few days at the Exposition under the intelligent guidance of an instructor, taking advantage of all the opportunities offered, should be equivalent to several industrial trips and plant visits.

By way of practical suggestion we offer the following: The students can be divided into groups and assigned to the study of exhibits of fundamental engineering equipment such as filters, evaporators, driers, etc., and required to make a written or verbal report for the benefit of the entire class. Lectures by specialists can be arranged in advance to be given by representatives of important exhibitors. Through the use of a stereopticon with reflectoscope attachment explanatory lectures can be given by the instructor based on the catalogs and other trade literature distributed at the Exposition. Meetings can be held for the discussion of new processes and equipment. Doubtless other means will suggest themselves for taking full advantage of the Exposition, but the principal thing is to take definite steps to get the students there in groups for two or three days. It is true that the Exposition is held just at the beginning of the school year, but it will well repay the effort to make use of it regardless of some slight inconvenience. Fortunately it is centrally located with respect to a great many colleges and universities.

Should Engineers Be Licensed?

IT IS DOUBTFUL if chemical engineers throughout the country are awake to the consequences of licensing laws that have been proposed or passed in many of the states. In fact it may be said that engineers of all classes were scarcely alive to the activities of a very energetic minority until bills had been passed affecting their right to practice. The unfortunate part of this lethargy is that whether he likes it or not, the engineer living in a state in which licensing is the custom comes under the terms of the law and finds himself restricted or hampered by incompetent legislation. The general attitude seems to have been one of *laissez-faire* in the thought that no particular harm could come from the licensing of engineers.

As a result of this attitude the movement has gone so far that many of those who are opposed to the policy feel that the most effective thing to do now is to guide and direct future legislation into the best channels. This is the view of the American Engineering Council. We think it is a grave question, however, whether any good can be accomplished from licensing engineers whose work requires the exercise of initiative, ingenuity, judgment or the creative faculties. It is conceivable that where the public safety and health are at stake licensing could accomplish some good. Thus engineers who are responsible for public works might be licensed with advantage to the community. But even this is questionable. The licensing system has not worked miracles with the medical profession. We still choose our physicians on recommendations other than those arising from the license to practice. So it is with chemical engineers, and we doubt not with many others. The stamp of state approval does not necessarily turn a poor engineer into a good one, and heaven knows plenty of poor engineers could get licenses.

New York is one of the states which has adopted the licensing system. The bill went into effect in April, 1921, and all engineers who are not licensed by April, 1923, will be subject to heavy fine if they attempt to practice. An examining board has been appointed to give examinations and issue licenses. We understand that the license entitles one to practice as an engineer without regard to the kind of engineering he is qualified to undertake. Being licensed, he may operate a chemical plant, design a skyscraper, build a bridge or lay out a system of sewerage! At least he is entitled to do these things as far as the license is concerned. It would certainly seem desirable to differentiate among engineers if they are to be licensed at all. But why license them? What do *Chem. & Met.* readers think about it from a chemical engineering viewpoint? We invite discussion.

Alas, Poor Potash, I Knew Him Well

ONE WEEK we get evidence of German pressure to eliminate the American potash producers, and the next week we receive manifestations that the American consumers of potash are very unfriendly toward the American industry. Now it is the National Fertilizer Association which objects to protection of the potash industry in this country. Every red blooded American, it says, would like to see the potash industry develop if it can be done along sound and permanent lines. Judging by subsequent sentences the sound and permanent lines seem to mean that American potash shall act as a kind of valet for the fertilizer industry and say "Yes, sir!" very loud whenever it is called.

If you object to American potash because it contains "too high a percentage of potash to obtain even distribution when used as fertilizer" and then object to it because the high freight rates in America militate against its use in potash consuming centers, you may still be consistent, despite the fact that the Panama

Canal makes cheap transportation possible from the producing points on the Pacific to the consuming centers on the Atlantic. But if the American potash were more dilute the freight would be higher. It looks as though the fertilizer industry wanted to have its potash cake and eat it too!

It is not strange that a consuming industry should object to protection for a producing industry. That happens all along the line. Textile manufacturers, in the opinion of some dye importing firms, object to adequate protection of dyes although they will protest vigorously if any reduction in the protection of textile goods is suggested. Similarly, some years ago the fight as to whether both zinc ore and spelter should be protected was bitter almost to the point of personal violence. As a country we do not seem to understand that when we start on a policy of protection all economically sound industries deserve like consideration. Protection of any industry inevitably must be paid for by the consumer. This is not an argument against protection, but it should invalidate the objection to a protective policy for any one article on that basis. We hold no more of a brief for potash than for any other American industry, but it seems that potash is about as hard pressed as any other chemical industry in an endeavor to stay alive. Therefore, if we stand in this country for protection, we should stand for protection of the potash industry, in which Americans have invested capital with the confidence that protection would be established. It seems to be only one more argument for a commission to determine and administer tariff rates in a manner analogous to that of the Interstate Commerce Commission. Such a commission will be non-partisan and expert. Some time this country will tire of the log-rolling, pork-barrel method of regulating vital industries. Speed the day! In the meantime the fertilizer industry ought to give fair and sympathetic consideration to the potash industry. If we read aright the trend in fertilizers, it is distinctly toward more concentrated products. Ultimately present methods will be abandoned and concentrated salts will come into their own. Foreign potash will not always hold the stage. Why not give a little thought to the next act on the program?

A Move to Kill Commercial Bribery

ON JUNE 1 the House of Representatives passed H. R. 10159, entitled "A Bill to Protect Interstate and Foreign Commerce Against Bribery and Other Corrupt Practices." This is the so-called commercial bribery bill. It is now in the hands of the Senate where favorable consideration is expected. The bill provides severe penalties for the payment of gratuities to employees for special favors: a fine of $3,000 or imprisonment for two years, or both. One of its questionable provisions is the granting of immunity to the person who first brings evidence of a particular illegal transaction. It is felt by many that this will lead to the development of a spy system and some concomitant evils. In spite of this the bill is generally considered to be a step in advance and one that should make considerable progress toward the elimination of a disgraceful commercial practice. This will be particularly true if prison sentences are imposed on 2 or 3 offenders. A fine would not be nearly as significant, but 2 years in prison would certainly be a strong deterrent.

The bill was aimed primarily at the dye industry, although that is a well-known offender. But excellent as the bill might be in this case we believe there is a surer remedy. The dyer in a textile mill is an important workman. It is in his power to make or break the mill. If his dyeing is successful, the material will be first grade and consequently high-priced goods. On the other hand, if he makes a small slip the material is relegated to the class of "seconds" and the price of such goods is considerably less. Thirty years ago and earlier the dyer occupied the same position with respect to the industry, but the employer gave him a pretty niggardly wage, somewhere in the neighborhood of $10 to $15 a week. Now the offering of a small wage to men in positions of responsibility is the surest way to foster a system of dishonesty. At any rate the practice of bribing dyers developed and dyes even now are sold on a basis of friendship and bribery. There are some firms that don the white garment of purity with regard to this point and yet practice it surreptitiously, either by means of Christmas presents or through a friendly and unscrupulous broker. So much for the origin and practice of the system.

We understand that a scheme for eliminating the bribing of dyers in German textile works was successfully instituted by a large German dye house, not through any virtuous motive, but because it was cheaper than bribing. According to this plan the textile firm was to set a certain cost which it was willing to incur for dyeing its material. This was to include the price of dyes and chemicals, salaries of the dye force, the overhead and amortization fund. Then if the dyer was successful in turning out a minimum of "seconds" the firm would agree to pay the dyer, in addition to his salary, all that he could save under that minimum cost. In other words, if a dyer was to cut the dyeing cost from 15c. per piece to 12c. per piece the dyer would get that 3c. in the form of a bonus. This plan puts a premium on intelligence, energy and good results. It brings the aims and desires of the employee into harmony with those of the employer; and when this principle is achieved, bills to prevent commercial bribery are unnecessary and ridiculous.

Why Not a Performance Standard For Carbon Black Plants?

A YEAR ago the U. S. Geological Survey announced that six plants producing carbon black made in 1920 less than one pound of carbon per thousand cubic feet of gas consumed. About thirty other plants made between one and two pounds of carbon per thousand feet of gas. In the recent report for the year 1921 the Survey gives the encouraging statement that some companies have attained a yield of 3.5 pounds of carbon per thousand feet of gas, a 75 per cent increase in yield above the maximum the year before. However, there evidently are still a number of plants making less than one pound per thousand, for it is recorded in the preliminary data just announced that one plant made as little as 0.2 pounds!

Carbon black is made from natural gas by incomplete combustion of the gas under more or less definitely controlled conditions. The percentage recovery of carbon from the gas is usually between 2 and 3 per cent. The thermal efficiency of the process is perhaps 1 per cent. These facts show that the carbon-black industry as now practiced in the United States still has problems of great importance on the score of technical efficiency.

The carbon-black industry has for some time also been the object of legislation. It has had to migrate from one gas field to another partly to secure gas at minimum cost, but also in part seeking always to keep ahead of that enlightened public opinion which precludes use of gas for carbon-black manufacture when there is demand for the gas for public utility supply and household use. It is time now to inquire whether the basis of legislation should not be changed.

It would be absurd to try to legislate this industry out of business, for the product of the industry is of great industrial importance. The public does, however, have the right to demand that the industry shall not be unduly wasteful in its manufacturing methods. The industry can well ask itself whether those plants which make less than one pound of carbon per thousand feet of gas burned should not improve their yields or be prevented from operating longer. If this question can be answered satisfactorily, it is quite likely that the industry will do much to eliminate the cause for criticism which has existed in the minds of state officials.

It is, of course, not feasible overnight to change a plant from one making 0.2 pound to one making 3.5 pounds per thousand. Moreover, maximum yield cannot be had without some sacrifice of the quality of the carbon black made. But given time any plant can reasonably be expected to reach at least a minimum yield in pounds per thousand or it should be compelled to cease operations. This would be not only in the interest of the general public, which wants the gas efficiently used, but also in the interest of the industry itself, which inevitably suffers most from unnecessarily poor technology. The time may never come when all will equal what is now the best, but certainly all of those now far below the average can reasonably be brought up to that performance which a majority of the plants demonstrate to be commercially feasible without undue sacrifice of quality of product.

Basing Wages On Performance

PUBLIC OPINION regarding the relations between employers and employed has changed materially in recent years. The feeling is much more general that the employee should receive a just proportion of the profits arising from the combined services of labor and capital. At the same time sound economics teach us that the sum total of wages paid cannot exceed the value of the goods which are available to the workman without that divergence tending to advance prices through competitive buying.

Accordingly the subject has been developed to a point where it is made plain that if workmen as a group are to obtain more for their wages their production as a whole must be increased and the question is how that is to be accomplished.

This question, instead of involving "the division between labor and capital" about which we have heard so much, is really a question of division between different classes of workmen. We have seen various labor leaders claiming that certain incomes ought to be paid the particular classes of men they represent, usually calling the sum "a living wage" with frequent reference to an imaginary "American standard." It is hardly to be supposed that these labor leaders do not know that they are claiming for their men more than the reasonable share of those men in the total production. It is a safer assumption that they know, but that they are in competition and are simply trying to get all they can.

An important problem, then, is that of increasing the total production of goods and the rendering of service, and then of allocating to each workman his share, in proportion to what he contributes in work.

There has been ample opportunity for everyone to observe that men in different classes of employment are not equitably remunerated, one with another, in proportion to the quantity of work they do. The market values of the work might be equal without the intrinsic value being equal, market prices of work being fictitious on account of various influences, including, just for one instance, the accident of one labor union having been more assiduous than another in controlling the number of apprentices.

The human element is the great factor to be considered. For example, it is common knowledge that in certain lines of work, such as construction, men are to be found who are inclined to nurse the job along. They do not know whether there is going to be another contract after this one or not. On the other hand the man in the factory, whether making bolts or bricks or what-not, is likely to feel that the better he works the longer his job will last. The coal miner, again, belongs to the other category, feeling that there is only so much coal to be mined in a year, hence he wants a six-hour day or indulges in a strike of a few months' duration.

The difference is in the conditions of employment, which need to be modified so that this vicious tendency of nursing the job should be eliminated. The great divergences in the quantity of work done now by different classes of workmen could be brought out by an intelligent study of how much workmen in different callings really do in a day, carpenters, bricklayers, coal miners, sheet mill rollers, pick and shovel men, railroad workmen and all others.

Responsible to Economic As Well as Business Laws

IN DISCUSSING one of its railway wage decisions the U. S. Railway Labor Board made the following statement:

> The labor board has never adopted the theory that human labor is a commodity to be bought and sold upon the market, and consequently to be reduced to stagnation wages during periods of depression and unemployment. On the other hand, it is idle to contend that labor can be completely freed from the economic laws which likewise affect the earnings of capital.

Thus it appears that another judicial body recognizes that labor and labor organizations cannot be exempt from the normal operation of economic laws. No impartial consideration of the subject could reach another conclusion.

Organized labor has consistently urged that the increasing cost of living made necessary increase in wages, and that labor was entitled to take advantage of the shortage of man-power through the acceptance of higher wages, or the expectation of a bonus from employers. No one will deny these rights and privileges if labor will at the same time admit that with decreasing cost of living and deflation in the industry, the employer has an equal right to expect reasonable reduction in wages and cancellation of bonus payments that may have been necessary during times of unusual industrial activity. It will be a poor rule that works only one way.

Readers' Views and Comments

Efficiency of Carbon Black Plants

EDITOR'S NOTE: Mr. Bubb at our request commented on a preliminary draft of the editorial in this issue entitled "Why Not a Performance Standard for Carbon Black Plants?" The comment, which follows, is so valuable that we take pleasure in publishing it in full.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I appreciate the opportunity to read your editorial. Your invitation to criticise it "vigorously" bespeaks a most commendable spirit of fairness. Except in a few points, I think your editorial admirable both in matter and manner.

Your argument that effort should be directed toward bringing all plants to the highest feasible standard of efficiency, instead of toward the destruction of an essential industry, is sound and convincing. Imperfections and inefficiency exist in most lines of manufacture. The remedy does not consist in suppressing the business or jailing the owner, but in devising more economical and efficient methods. But all legislation enacted, or attempted, against the carbon black industry has aimed, not to improve, but to destroy.

Three Criticisms Advanced

Three criticisms of your editorial occur to me.

WHOLE TRUTH NOT STATED ABOUT PERCENTAGE RECOVERY

1. In the first paragraph it is stated that "the percentage recovery of carbon from the gas is usually between 2 and 3 per cent." This is the truth, but not the whole truth. The inference is that the efficiency of the process is to be judged solely by the weight or volume of *carbon* recovered.

The element carbon is exceedingly common. It exists in many forms having a black color, such as coal, lignite, coke, animal and vegetable chars, graphite, gas-retort carbons, etc. These substances are black and are chiefly carbon, but they are very far from being "carbon black."

EFFICIENCY SHOULD BE JUDGED BY QUALITATIVE STANDARD

What is commercially called "carbon black" is a rather complex *pigment*, possessing certain remarkable properties—viz., unique brilliance and intensity of color, complete freedom from hard or gritty particles, unequaled minuteness of division, covering power when mingled with oil, and reinforcing power in rubber compounds. W. F. Weigand, the well-known rubber chemist, states that each cubic inch of carbon black contains 1,905,000 square inches (about one-third of an acre) of surface. The manufacturers' problem is not simply to dissociate the largest possible amount of carbon from hydrogen, but to make a uniform pigment possessing these unique properties, on which utility and value altogether depend. In other words, efficiency, as applied to this industry, must be judged by a qualitative more than a quantitative standard. Quantity alone means nothing.

Thus far no one has been able to attain the requisite power except by collecting the smoke or soot of a hydrocarbon gas flame. Yield and quality seem to be inseparably related. The higher the grade of black desired the greater the volume of gas consumed per pound.

HIGH PERCENTAGE OF RECOVERY MEANS TOTALLY INEFFICIENT CARBON BLACK

Several years ago a well-known industrial chemist, decomposing gas under intense heat in a retort, in the presence of a catalyst, succeeded in obtaining from 8 to 10 lb. of carbon from a thousand cubic feet of gas. But the material was grayish, gritty, utterly deficient in color and tinctorial power—in short, lacking in the very properties which impart value and usefulness to the product employed to print books and newspapers, make carbon papers, reinforce rubber compounds, etc. From a quantitative standpoint the process had an efficiency of more than 30 per cent. From a qualitative standpoint it was 100 per cent inefficient, because nobody wanted or could use the resulting product.

BY-USES OVERLOOKED BY CRITICS

Critics of the present process also overlook several other facts. Of course the "natural-gas gasoline" is first extracted from the gas. Next, advantage is taken of the expansion of the gas to furnish motive power to run the factory. This is done by piping the gas at line pressure into the cylinders of a steam engine, where it is expanded, thus furnishing power without expense, except for lubricating oil. The process is continuous and automatic and from a mechanical standpoint exceedingly efficient and economical.

AS TO "ENLIGHTENED PUBLIC OPINION"

2. I do not think the statement that the industry "has had to migrate from one gas field to another seeking always to keep ahead of enlightened public opinion" is quite a fair presentation of the case.

The fact is that the carbon black makers try to obtain their raw material, natural gas, where it is cheapest and most abundant. This has led them to sell their gas as soon as markets are created in which it can be sold more profitably than it can be used in their own business, and to undertake the pioneer work of developing new gas fields. This has not been compulsory. On the contrary, neither Pennsylvania nor West Virginia, the states in which the industry has been longest established, has ever passed any law forbidding or in any way restricting it. And I am not sure whether an "enlightened public opinion" would condemn the use of natural gas for a product so essential to the enlightenment of public opinion as printer's ink.

There is much common sense in G. A. Burrell's recent article in the *Oil and Gas Journal* in which he says: "It is hard to see why printer's ink, tires, etc., do not add as much to the happiness and comfort of the people as the burning of natural gas for heat and light."

YIELD OF 3.5 LB. PER THOUSAND DOUBLED

3. One other statement in your editorial needs

have attained a yield of 3.5 lb. per thousand." Possibly this may be attainable. Certainly nobody has yet commercially attained so large a yield of a true carbon black, possessing the properties and range of utility above mentioned.

Factors Governing Yield

Passing to the questions asked in your letter, I would say that the yield depends largely on two factors: (1) The composition of the gas. (2) The quality of black desired.

Composition of the Gas

Actual experience of our company has proved that the *identical factory*, when removed to a new location and using leaner gas, may show a diminution in yield of as much as 30 per cent. This is of course due to the difference in the composition of the gas. The following analyses of gas from three different states will illustrate:

	No. 1 Per Cent	No. 2 Per Cent	No. 3 Per Cent
CH_4	80 5	94 12	46 45
C_2H_6	18 0	3 44	43.10
CO_2	0.0	0.40	0.96
N_2	1 5	2.40	9.49

A standard type factory, operating on No. 1 gas, averaged 1.4 lb. per thousand cubic feet. The same factory, removed to a new location, using No. 2 gas, produced only 0.9 lb. per thousand. A factory of the same type and design, similarly equipped and operated, yielded an average of 1.75 lb. from No. 3 gas.

It is also a well-attested fact that more black will be produced by the same factory in the same field as the field grows older. The reason is that the leaner and lighter gas comes off first.

Grade of Black Produced

I have already pointed out that the yield can be materially increased by sacrificing quality. It is also true that the highest grade gas blacks, such as are used for the best inks, finest lacquers and varnishes, etc., invariably require *several times as much gas per pound as the ordinary grades.* Undoubtedly the yield of only 0.2 lb. mentioned by the Geological Survey represents the results attained at a factory manufacturing high-grade blacks. These blacks are produced only in limited quantities, and command a price of from 35 cents to 45 cents per pound, as compared with from 8 cents to 12 cents for ordinary grades. In such a case, one unacquainted with the grading of blacks might draw a wholly erroneous inference from difference in yield, which is explained by the differences in quality of the product.

Some Comparisons on Losses

While we are on this subject of efficiency, at the risk of imposing on your patience, I should like to draw a few comparisons.

Distribution Loss in Gas for Domestic Use

When gas is distributed for domestic use there are losses all the way, in transmission, in distribution and in utilization. The U. S. Geological Survey states that in 1919 the total waste of natural gas in production and transmission was 58,943,631,000 cu.ft. Carbon black factories, located in the field, in immediate proximity to the wells, are virtually free from transmission and distribution losses. According to S. S. Wyer, where gas is produced and distributed to domestic consumers, the domestic consumer's actual utilization is 8 per cent, the total losses being 92 per cent. Tests made by the bureau of home economics of the Ohio State University on gas ranges, burning gas at 4 or 5 oz. pressure, show an efficiency of 13 per cent on the gas supplied to the burner, which would be equivalent to about 6.5 per cent on the gas drawn from the well.

Loss in Gas and Coal for Power Plants

Oliphant's data on use of gas under the boilers of an ordinary well-pumping steam engine give an efficiency of 2 per cent. I have also seen in the public press the statement attributed to Dr. Steinmetz that the efficiency of the lava-tip burner used for lighting is less than 0.5 per cent. In an article published last October in the *India Rubber Review*, W. F. Clark, a specialist in power plant engineering, states that out of one ton of coal in the ground the average recovery brings to the surface 1,400 lb., the power to operate the mine takes 100 lb., and the coal actually turned into work at the point of application in small plants is 76 lb.

Undoubtedly some of these losses could be avoided; undoubtedly they ought to be. But no one advocates prohibiting the use of gas ranges, lava-tip burners or gas-fired boilers.

Again to quote Mr. Burrell: "One of the chief arguments used against the carbon black industry by its opponents concerns the low yield as compared to the theoretical yield obtainable. One might as well decry the fact that in burning natural gas only about 5 to 20 per cent of the gas is converted into useful work."

Williamsport, Pa. N. B. Bubb.

Ido, the New Universal Language

To the Editor of Chemical & Metallurgical Engineering

Sir:—In a recent issue of your paper I noticed a letter by G. W. Lee, of the Esperanto Association of North America, written in answer to one I wrote in regard to Ido.

I am sorry that I cannot agree with him regarding the status of Esperanto in Europe, but I cannot. The spread of Ido since the war is great, and Esperanto has met with some reverses. (Ido also has had its reverses.) But the superior qualities of Ido are gradually bringing it to the fore.

There are about sixty existing systems of an international language, very few of which are at all worth considering. Many of them have come into existence, as has Anglido, by being created by someone who disagrees with the various academies and societies that have charge of the propagation of the language.

Mr. Lee expressed the wish that I place Esperanto, Ido and Esperantida side by side and compare their relative merits. I am unable to do so with Esperantida, but I have done so with Esperanto and Ido. In fact I subscribe to a magazine published in both languages. And frankly, the difference between Esperanto and Ido is very great. In addition to the six special letters of Esperanto, its vocabulary is limited, and in order to express the thoughts that are wholly international one must often use makeshift expressions.

Now, I wish to make the following proposition to Mr. Lee, and I hope that he will accept. That the Esperantists, Idists and the proponents of all other language systems get together and form an "International Language Association of America." Such an

association would devote itself to the propagation of the idea of the international language. That such an association shall publish a journal, whose pages will be open to the proponents of all languages, the journal to have the principal articles published in Ido, Esperanto Romanal, etc. (that is, the principal short articles). The body of the magazine shall be devoted to articles in English, about the languages and shall contain the authentic world news of such languages. In fact, it shall serve as a clearing house for all systems, and shall enable the idea of the international language to permeate all places and enable all those who would desire to study the international language to judge for themselves the merits of the languages and to select that which most appeals to them. As a representative of Ido I speak. I shall welcome advances from Mr. Lee in regard to this matter, and I am confident that if we get together and work together the cause of the international language will not lose out. I am an Idist because I believe that Ido is the logical solution of the problem of the international language, but if the public shows that it wants some other language, then I shall be content to accept what the public wants or what some authoritative body may decide upon as an official international language.

Elyria, Ohio. EARL WALTER SUTTON.

Melting Losses in an Aluminum Furnace

In the notes on John A. Lange's paper "Melting Aluminum for Rolling Into Sheet," contained in the report of the Foundrymen's Association (*Chem. & Met. Eng.*, June 14, 1922, vol. 26, p. 1110) the furnace losses are shown ten times too large. When melting virgin metal 0.9 per cent was lost; clean mill scrap lost 1.6 per cent, and oily stamping scrap lost 3.1 per cent.

News of the Italian Chemical Industry

FROM OUR SPECIAL CORRESPONDENT

GENOA, June 5, 1922.

WITH the hope of encouraging research which will result in substantial progress for the Italian chemical industry, the Associazione Chimica Industriale, of Turin, has arranged for a prize competition in which 5,000 lire has been offered for the best scheme proposed for the utilization of some chemical waste product, or for the new use of some chemical already known. The Federazione Fabbricanti Acidi and the firm of Stabilimento Ing. A. Vitale of Rumianca have also offered a prize of 3,000 lire for the most practical new use suggested for sulphuric acid. A similar prize is also offered by the chlorine producers. It is generally well known that, as a result of the war, considerable excessive manufacturing capacity exists in both of these industries. Since the Armistice, many firms have had to reduce their production on account of the large unsold stocks which had accumulated. The situation has been further complicated by the crisis in other Italian industries. Italy ordinarily produces more sulphuric acid than is consumed and therefore boasts of a modest export trade in this commodity. The production in 1918 reached the total of 835,440 tons. During the past year, imports have been practically nil, while exports amounted to 576 tons, of which quantity Switzerland received 328 tons and Egypt 14 tons.

The demand for superphosphates was scant during tinued at their usual rate. Consumption of this commodity is somewhat seasonable and the works are looking forward generally to good business later. Cyanamide is in demand, especially in some regions where its use has become rather thoroughly established. The demand for nitrate of soda and copper sulphate is also unusually good for this season. In the case of the latter commodity, the independent producers have had to meet the competition of plants which were working on contracts from the co-operative agricultural federations, prominent among which is the Società Anonima Vercellese Industria Solfato "Avis," with a capital of 2,000,000 lire.

The continued difficulties in the sulphur industry have resulted in the closing of many of the Sicilian mines, thus throwing thousands of operatives out of employment. In the hope of bettering this situation, a law has been proposed in Rome authorizing the Consorzio Solfifero Siciliano to issue obligations to the extent of 100,000,000 lire, and also requiring that a cash concession of 13,000,000 lire be paid to the same institution by the Bank of Sicily.

The production of Sicilian sulphur in 1921, according to Consul Edward T. Nathan at Palermo, amounted to 240,049 tons, or practically the same as in 1920, of which 80,000 to 90,000 tons are consumed annually in Italy. The exportation amounted to only 105,063 tons in 1921 while 188,868 tons were exported in 1920. As a result the stocks at the various mines on Dec. 31, 1921 were approximately 273,579 tons, as compared with 147,886 at the close of the preceding year.

At a meeting of delegates of the sulphur consortium and more than 200 sulphur-mine owners, held on April 27 at Palermo, resolutions were passed disclaiming acquiescence in the failure of the Government to grant the provisions requested, and the resignation of the consortium council was tendered. The crisis in the sulphur industry is due to the high cost of production, wages representing about 50 per cent which, combined with costly methods of extracting and refining, has led to a decline in exports through the inability of the producers to meet competition. As a result most of the Sicilian mines are either shut down or working on part time.

PETROLEUM RESOURCES

Among the important events of the past month was the signing of a commercial agreement between Italy and Russia, whereby the former country is to obtain extensive supplies of petroleum, coal and mineral oils. Some effort has also been exerted toward reaching an agreement with Rumania for the purpose of securing the free exportation of their crude oil which will be treated in the refineries at Trieste. It has also been announced recently that several new sources of petroleum have been discovered in Italy, at San Giovanni Incarico and at Ripi.

With the annexation of the Terento and Istrian regions, Italy came into the possession of the Idria mercury mines, which are third in importance as compared with the other mines of the world. In these mines, free cinabar is found in calcareous dolomites and occasionally in the carboniferous layers. The different minerals contain from 0.5 to 50 per cent of mercury. The yields of the mercury mines during 1920 were but 460 kilos per workman against 718 kilos in 1918. It is not known at this time whether this lower output is due to the depreciation of the deposits or to less intensive exploitation

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

LONDON, June 15, 1922.

IT IS pleasant to be able to record a further improvement in business for nearly all classes of products, although there have been no important changes in market prices. Both for home and export chemicals are in good inquiry, and even in dye intermediates there is every prospect of improving demand. The end of the engineers' lock-out, the reduction in the bank rate and other factors have done much to restore confidence, and in financial as well as in trade circles there is talk of a minature boom before the close of the year. The engineering dispute has done far more damage to the chemical industry than is generally realized and in seriously reducing coke-oven output, sulphate of ammonia production as well as the trade in basic slag has been affected. On the other hand, heavy chemicals continue to do well and caustic soda, for instance, has been shipped in quantity to the Continent. There has also been a material increase in the quantity of Scotch coal shipped to Germany.

CRITICAL DAYS FOR THE DYESTUFFS INDUSTRY

"Of making books there is no end and too much learning is a weariness to the flesh" is a quotation in which "dyestuffs" might well be substituted for "books." The trials and tribulations of the manufacturer have been ventilated *ad nauseam* and the idea that the British Dyestuffs Corporation is negotiating with the German I. G. to impart its "secrets" seems almost the last straw. Whether this is partly the reason for Dr. Levinstein's offer to resign from the board of directors in order to express his dissent from their technical policy is a matter of conjecture. The *Times*, however, has really surpassed itself by a journalistic brainwave which recommends the handing over of the required information as partial satisfaction of reparations payments! Actually the Germans are inclined to treat with some concern the progress made in the British dyestuffs industry, and the prices paid for dyes made abroad are not considered prohibitive by users. It seems doubtful whether an arrangement similar to that made with France would be tolerated, and public opinion is on the whole determined that the country shall not slip back into its pre-war dependence on foreign countries. The annual meeting of the British Dyestuffs Corporation will be held next week and may throw some further light on these vexed questions. During the current year there has been a loss in trading of about $4,500,000, mainly on account of drastic writing down of stocks to correspond to current prices.

FURTHER DEVELOPMENTS AND NEW PROCESSES

The Brondse process for oxidizing, browning and coloring iron, steel and non-ferrous metal articles is likely to find extensive applications. The ordinary methods involve heat-treatment or chemical action for prolonged periods, whereas the process under review is an electrolytic one requiring a few minutes' treatment only in simple apparatus, and giving a variety of colors and finishes varying from brass and copper to shiny black. Accurate parts such as micrometers and gages can also be treated, as there is neither corrosion nor increase in size and it is unnecessary to remove rust as it is automatically removed in the process. It iron is actually deposited at a very low cost, and being extremely resistant to chemical action as well as to mechanical abrasion, the process should find increasing application in the chemical industry. Some well-known experts have been retained for the technical development of the Plauson colloid mill in this country, and among more recent applications the use of suspensions of bitumen and asphalt in water is indicated as a promising substitute for the present method of covering roads with the hot molten product. The use of titanium oxide as a paint material is also attracting attention and the Norwegian product has been found satisfactory in admixture with about three parts of barium sulphate and also in suitable proportions with other compounds. Sir George Beilby, director of the Fuel Research Station, recently delivered an address on his researches on the structure of coke, and these, together with the information contained in the report on low-temperature carbonization just issued, are considered to be of the greatest importance. Beilby was able to produce coke of an apparent density of 1.33, of which the internal reactive surface is quite equal to that of wood charcoal of half the density. The station is carrying out further investigations in regard to automatic carbonization, briquetting before carbonization and improved means for increasing the strength of briquets.

BRITISH CELLULOSE WRITES DOWN ITS CAPITAL

Drastic action in this case was, as foreshadowed in these notes, almost inevitable, but the formation of a holding company which takes over the Cellulose company's power station and a large slice of the debentures and preference shares in return for financial assistance has not been regarded as a favorable arrangement. The government and the preference shareholders are the chief sufferers, and it remains to be seen whether the reconstruction, together with the promised Swiss technical assistance, will enable the company to manufacture marketable products profitably, or whether further drastic steps will become necessary.

GENERAL NEWS AND NOTES

The annual meeting of the Society of Chemical Industry will be held in Glasgow early in July and Dr. Ruttan, Dr. Ellwood Hendrick and other visitors will receive a very hearty welcome both there and in London. Dr. Ruttan is to address the Chemical Engineering Group and the Chemical Industry Club on "The Training of the Chemical Engineer," and the Institution of Chemical Engineers, which was brilliantly inaugurated on May 2, will be well represented. The Institution is working in close co-operation with the American Institute, but is meeting with the usual difficulties in regard to its relationship and co-ordination with other qualifying bodies such as the Institute of Chemistry and the Institution of Civil Engineers.

The chemical ingredients of gas mantles are now subject to duty under the safeguarding of industries act and a further duty is now suggested under part 2 (dumping and depreciated currency) of the act. The inquiry has been adjourned to enable the German trade association to be represented, a procedure for which there is no precedent and which has occasioned considerable surprise.

Sir T. H. Holland is the new rector of the Imperial College of Science and Technology in succession to Sir

Niagara Falls Meeting of the American Institute of Chemical Engineers

Strong Technical Program, Interesting Excursions, Pleasant Entertainment Features and Scenic Beauty of Niagara Combined to Make Meeting a Great Success —Next Meeting Possibly at Richmond, Virginia

NIAGARA FALLS in now just such another joyful memory for the American Institute of Chemical Engineers as is Baltimore, Detroit, Savannah, Boston, New Orleans and so on back with half-yearly jumps until even the secretary, Dr. Olsen, becomes a little vague as to where the Institute convened. Niagara Falls was a happy choice of place, with the thrilling cataract—a kind of symbol of America—as a background and its vicinity alive with industries which allure the chemical engineer. It was a characteristic convention—stimulating, vigorous, live. If you ask a member of the Institute why he goes to the meetings he will give you any one of a score of reasons; the papers, the discussions, the industrial excursions, the meeting with other men in the profession, etc. But whatever the reason, twice a year about 20 per cent of the total membership of the Institute convenes, so there must be something in it.

The cub reporter had a memorable time which began when he pinned the blue badge on his lapel and ended when he left the Shredded Wheat factory four days later in a dash to catch the Buffalo train. It will be a long time before any of us forget the little page with a hundred silver buttons on his coat and the booming bass voice—"Call for Mister Reese." The asthmatic bus in Toronto which took thirty of us out toward Eastman's kodak factory is another memory. It broke down five times and finally died half a mile from the plant. Nor will we forget the enthusiastic songfest that was staged by the second carload coming back from Buffalo to the Falls. Led by Mr. de Beers and encouraged by the example of Messrs. Marshall, Stokes, Tunison and Richter, there was almost collegiate harmony throughout the trip.

Still another episode is remarkable. A new kind of game was developed by part of the crowd which went to see the Hydro-Electric power plant. It requires seventeen automobiles filled with people, all bound for a definite point. None of the people in the cars must know the location of the destination. A leader is chosen who starts off on what he believes to be the worst road in the vicinity—not necessarily in the direction of the destination. When the road becomes good, the leader is deposed and another leader elected who knows a worse road. A broken spring counts 10 points and "a good time may be had by all." By a process of elimination the destination is reached—and the Hydro-Electric plant was magnificent.

The local committee is to be congratulated upon the arrangement and plans which were excellently conceived. G. Prescott Fuller was chairman of the Niagara Falls committee and was assisted by Messrs. Lyster, Kellogg, Mauran, Lidbury, Tone, Snowden and Sergeant. An especial palm should be added to the decoration of chairman, and Messrs. Rippel, Howard, White, Spalding, Kerr and Heritage. The Buffalo program moved with even greater smoothness, if that is possible. The ladies were entertained by a committee headed by Mrs. A. H. Hooker and Mrs. C. B. Morey. Below is given in condensed form the program which was carried out as originally planned.

MONDAY, JUNE 19, 1922

8:00 a.m. Registration, Hotel Clifton, Niagara Falls, Ont.
9:30 a.m. Reading of Papers.
1:30 p.m. Luncheon at Hotel Clifton.
2:15 p.m. Automobile trip through Niagara Falls, Ontario, including inspection of Niagara Falls plant of Hydroelectric Commission and new power canal.
8:00 p.m. Public Lecture at Hotel Clifton.
"Geology of the Niagara district," by John Jackson, superintendent of the Queen Victoria Park at Niagara Falls, Ont.
"Niagara Power Development," by John L. Harper, Chief Engineer of the Niagara Falls Power Co.

TUESDAY, JUNE 20, 1922

8:10 a.m. Special cars for Queenston via gorge route, Canadian side.
9:00 a.m. Boat for Toronto.
9:15 a.m. Business session on boat.
12:30 a.m. Luncheon on boat.
1:00 p.m. Arrive in Toronto.

1. Visit to Kodak factory and automobile sightseeing through the city.
2. Visit to plant of the Consumers Gas Co. and rubber factory, followed by automobile trip through the suburbs.
3. Automobile sightseeing trip through the city.

5:45 p.m. Boat for Lewiston.
6:00 p.m. Dinner on Boat.
8:30 p.m. Arrive in Lewiston; special cars for Niagara Falls via gorge route, American side.

WEDNESDAY, JUNE 21, 1922

8:00 a.m. Special cars for Buffalo leaving Hotel Clifton.
10:15 a.m. Meeting at Hotel Lafayette. Papers.
1:00 p.m. Luncheon, Hotel Lafayette.
2:15 p.m. Automobile trip around Buffalo. Opportunity was afforded for visits to the following plants: Lackawanna Steel Co.; Wickwire Steel Co.; Buffalo General Electric Co., Steam Power Plant; Dold Packing Co. and Larkin Company.
8:00 p.m. Smoker, Hotel Lafayette.
10:30 p.m. Special cars for Niagara Falls.

THURSDAY, JUNE 22, 1922

9:30 a.m. Meeting at Hotel Clifton. Papers.
1:00 p.m. Luncheon at Hotel Clifton.
2:15 p.m. Automobile trip, Niagara Falls, N. Y. Optional trips to the following: Hooker Electrochemical Co.; Niagara Falls Power Co.; Niagara Wall Paper Co.; Kimberly-Clark Paper Co. and Shredded Wheat Co.

Visit to the Ontario Hydro-Electric Power Commission

On Monday afternoon the members took an automobile trip to see the famous cut and power station of the Ontario Hydro-Electric Commission. Water is taken from a point above the first rapids and delivered at a point below the whirlpool where the level is that of Lake Ontario. This gives a maximum drop of 315 ft. —over 150 ft. higher than the drop obtained by the power companies at the Falls. In order to accomplish this it was necessary to dig a very deep canal, 35 ft. of which is lined with concrete. It winds through the country in a rough semi-circle for a total length of 13 miles. The excavation work is prodigious and has been fully completed. The power house is now under construction, although two 55,000-hp. turbines have been installed and are now operating. Each turbine is fed by a 15-ft. diameter standpipe. The ultimate plan calls for nine such installations, the largest in the world, the total expenditure for which will be in the neighborhood of $70,000,000. The engineering is on a vast scale and it is an exceedingly impressive sight.

Public Lectures on the Niagara Gorge and Power from the Falls

That evening two public lectures were given, the first by John Jackson, superintendent of the Queen Victoria Park at Niagara Falls, Ontario, on the subject, "The Geology of the Niagara District." He traced the history of the Niagara gorge and showed the reasons for the narrowing and widening of the gorge at various geological periods. The two narrow parts of the gorge were undoubtedly caused by the fact that Lake Huron had another outlet to the east which drained a great deal of the water formerly going over the Falls. At these two periods in the geological history of the gorge there was undoubtedly somewhat less than 20 per cent of the water going over the Falls than at present. At other times, due to a rise in the land, the Falls were almost as large as they are now.

THE POWER OF THE FALLS

John L. Harper, chief engineer of the Niagara Falls Power Co., spoke next on Niagara power development. Mr. Harper's talk was most enjoyable and he developed a number of interesting points. He showed by statistics that at least twice as much water could be withdrawn from the Falls as is now being used and still have the scenic effect improved, if anything, over its present condition. His suggestion was that islands be constructed at appropriate points in the Canadian gorge to distribute the water over there. The Falls would then resemble more the effect produced by the American Falls, an accomplishment which should be perfectly practical, he said. At the present time, about 20 per cent of the water which normally would go over the Falls, is being used industrially. Another 20 per cent could easily be extracted without materially damaging the scenic wonder. Mr. Harper told of the new turbines which have been recently contracted for by the Niagara Falls Power Co. of a size even larger than those now installed by the Hydro-Electric Power Commission of Ontario. Each unit will have 70,000 hp. capacity. Splendid photographs and moving pictures of the Falls were shown by the lecturer.

The Toronto Trip

The trip on Tuesday to Toronto by way of Queenston and the boat on Lake Ontario was most enjoyable. The day was perfect and the sail across the lake a great treat. The inspection of the city of Toronto and of its various industrial plants was also interesting. Many expressed great surprise that Toronto was such a tremendous city, the reported population being over 700,000. The boat trip back landed us at Lewiston, on the American side, and we took the famous gorge trip along the Niagara River at the foot of the great cliff. The great volume of water which goes over the Falls is more evidenced in the gorge than anywhere else. The swirl is very impressive and mountains of water pile up in almost terrifying heights.

Industrial Buffalo and an Air Trip

Wednesday took us to Buffalo, where a number of very large industries opened their doors to us. Five separate trips were conducted to the Lackawanna Steel Co., the Wickwire Steel Wire Plant, the Dolt Packing Co., the Buffalo Steam Power Plant and the Larkin Co. In addition three members of the Institute went up in an airplane and saw Buffalo from the air. This opens up a new possibility. Show visitors the city by using the air route. Each of the Institute members expressed great enthusiasm for the air route and remarked on the unusual and complete perspective which can be obtained in the air.

After the industrial visits, a tour of the city was made by automobile, the residential part of Buffalo being unusually beautiful on account of the many trees.

In the evening a very enjoyable smoker was held at the Hotel Lafayette. The Institute opens its doors at its meetings on its plant trips, and in its business sessions, but its smokers must be a fraternal secret. Besides it would be wise on our part to refrain from comment because of the possibility of domestic difficulties among the members if it became known that the performers at the cabaret were extremely good looking.

A unanimous and enthusiastic vote of thanks was passed to the committee in charge of the smoker.

The meeting closed on Thursday with an inspection of some of Niagara Fall's industries. Of course, it was not unexpected that the industries at the Falls were in general unwilling to open their doors. Many of the industries depend for their very life on the secrecy of their processes and they will all do everything for visitors except show them the inside of their manufacturing plants. Tea at the Niagara Falls Country Club was tendered the members as a parting function by the local committee.

Important Business Transacted

The business meetings of the American Institute of Chemical Engineers are always worth-while. The Institute is a leader in so many activities that the questions discussed are always vital and pertinent to the chemical engineer whether he be a member of the Institute or not. Records of previous meetings were approved and an extensive report of the Council meetings was made. Among the subjects discussed at the Council meetings were local sections of the American Institute of Chemical Engineers. Provision was made for such a local section where there were over ten members in a city. Meetings were to be held four times annually and close contact maintained with the national body. In some cities there would obviously be a call for such an organization and in other cities it would be somewhat superfluous.

Appropriate resolutions were adopted by the council upon the death of three members, A. W. Ayer, William C. Carnell and Charles Baskerville.

Finally, the council has outlined a program of co-operation with the Institution of Chemical Engineers, the newly formed British body. The suggested basis of co-operation was first, to print the names and addresses of both societies in the membership list of each society. Second, to grant all privileges to members of either society in the other society, except the privilege of voting at meetings. Third, to send a copy of all bulletins issued by the society to the secretary of the other society, so that he might make the proper disposal of it and bring it to the attention of his members if it was important. Fourth, to make publications available to members of both societies at cost price. It was voted to donate a complete set of the transactions of the American Institute of Chemical Engineers to the Institute of Chemical Engineers.

The secretary reported that 27 active members and 4 junior members had been elected during the past six months, bringing the total membership to 1 honorary, 440 active and 104 junior members.

The Committee on Patents reported that the Lambert bill carrying with it half a million dollars additional appropriation for the patent office, had been passed and that the committee on patents of the Institute had worked with the National Research Council patent committee in furthering this bill. It was also announced that President Howard had been instrumental in inserting a working clause into the patent bill whereby it becomes necessary for a patent to be worked in this country inside of two years or it is declared invalid. This is in the interests of American industry so that foreign companies cannot take out patents in this country and hinder American manufacturers.

Engineering Abstracts

The committee on engineering abstracts told of the conferences with E. J. Crane, editor of *Chemical Abstracts*, one of the journals of the American Chemical Society. Mr. Crane has volunteered to give more space to patents and engineering articles. The committee recommended that better abstractors of engineering articles and patents volunteer to undertake this work. At the present time it is wholly unfeasible to publish an engineering abstract journal. The duplication in work would be great and the cost would be excessive. This, however was considered seriously as a future possibility.

VIEW OF THE FALLS FROM THE AIR, HOTEL CLIFTON IN THE FOREGROUND

The place for the next meeting was discussed at some length and the secretary was instructed to discover the points of interest of Richmond, Va., as an industrial center. If favorably considered, the council was empowered to decide upon it as the meeting place.

A committee was appointed to co-operate with the American Institute of Mining Engineers in regard to the licensing of engineers in New York State. Successful opposition to the licensing of chemical engineers has been carried out in Massachusetts and in Ohio. It seemed to be the sentiment of the meeting to oppose the licensing plan.

Chemical Engineering Education

Perhaps the most important subject discussed at the meeting was the subject of chemical engineering education. The council reported that a conference on the report of the Institute committee on education between the colleges and the technical men in industry had been called in Brooklyn in May and that this conference had been extremely successful. After considerable discussion it was voted to appoint a committee of eleven, all members of the Institute, composed of six technologists and five educators to carry out the details of the report. The thirteen points adopted by the conference in Brooklyn leave a great deal of detail work to be completed, such as the standardization of nomenclature and the proper weighting of courses.

It was suggested and enthusiastically endorsed as a function of this committee, that after due deliberation it should aim to differentiate good and bad chemical engineering courses and approve the courses in institutions which were of the proper standard. In this way the general tone of chemical engineering education could be more effectively improved than in any other way. This is the same function which the American Medical Association has adopted and it has practically completely eliminated the fly-by-night medical schools. It was the general sentiment of the meeting that the work of this committee would be watched with great interest and that it was possibly the most important work the Institute has in hand.

Technical Papers Presented

The first paper was presented by Peter S. Gilchrist and was entitled "Modern Methods of Concentrating Sulphuric Acid, Including Concentration of Sludge Acid and Acidproof Masonry Construction." This paper appeared in the June 24 issue of *Chemical and Metallurgical Engineering* to which you are herewith referred.

L. A. Thiele's paper on "Increased Capacity of Cascade Systems" describes a special corrugated bottom cascade basin through which the acid travels in a wave-like motion. Such a basin has an effective heating surface equivalent to 3 times that of a basin without corrugation and this gives greatly increased heating capacity. A string of 50 of these basins produced from 16 to 18 tons of 93 per cent acid. The basin is patented under U. S. Patent 1,380,689. Application of the same principle to a still was shown, this being used in the production of gasoline, oils, fats, greases and in the recovery of volatile solvents. A still 3-ft. 6-in. in diameter and 9-ft. long was shown to contain 150-sq.ft. of effective heating surface and to have a capacity of 2,500 gal. of gasoline per hour.

An abstract of a paper by L. J. Michael and J. R. Withrow on the "Solubility of Quartz Packing in the Glover Tower," outlined very briefly some work which had been done on this problem. Careful calculations seem to indicate the impossibility of explaining the contraction in the Glover tower packing as being due to the solubility of silica in acid. It was probably due to the fact that the Glover tower had been allowed at various times to cool off and then had been reheated. The unequal contraction and expansion resulted in a rearrangement of the packing and an apparent loss. The discussion which followed this paper seemed to confirm this point of view.

Cifford B. Carpenter read a paper on "Concentrating Dilute Nitric Acid Solutions" by himself and Joseph Babor. He apologized at first for the errors which had appeared in an article by him published in *Chemical and Metallurgical Engineering* last February,[1] due to the fact that the standard succinic acid solution used had been found to be inaccurate. The work had been repeated and the revised result will be published in an early issue of *Chemical and Metallurgical Engineering*. From the data which is presented in this paper it will be possible to predict the fractionating column which will be necessary to produce a given result. The paper aroused much favorable remark and F. C. Zeisberg, of the du Pont company, who has done considerable work along this line, expressed his commendation of this work.

Mr. Zeisberg then read a paper on "The Thermal Considerations of Sulphuric Acid Concentration." This article appears in this number of *Chemical and Metallurgical Engineering* and therefore no abstract will be necessary.

P. J. O'Gara Discusses Sulphur Dioxide and Fume Problems

The Institute was extremely fortunate in hearing P. J. O'Gara discuss the nine years of research which have been carried out under his direction for the American Smelting & Refining Co. The research is of the most comprehensive nature and was designed to study the effect of sulphur dioxide and other fumes on vegetation. Dr. O'Gara himself is a plant physiologist and not a chemist but his handling of the chemical problems which developed in the course of the research was always deft. He first discussed the various types of fume cabinets and showed the various objections to them. His own cabinet, which has been critically examined by every man in that field, was the result of overcoming the difficulties in the earlier cabinet and now can be assumed to be almost an ideal cabinet for this kind of work. Troubles with the earlier cabinets were due to the lack of circulation, the disregarding of the humidity, light and other conditions, the unknown absorption of SO_2 by plants and consequent variation in the gas concentration in various parts of the cabinet, etc.

Dr. O'Gara's experiments were carried out in the field on growing crops. Extensive and very complete records were kept of all experimental work, accurate analyses of the gas used was made, light conditions and humidity conditions were recorded. The conclusions reached are extensive and valuable and it is our privilege to announce that Dr. O'Gara's work will appear in subsequent issues of *Chemical and Metallurgical Engineering*. A great deal of valuable data have been obtained from a purely scientific standpoint and a unique amount of information has been gathered on crop injury and on

[1] *Chem. & Met. Eng.*, vol. 26, No. 10, March 8, 1922, p. 443.

the cure for such injury. The relation of stack height to crop injury has been studied carefully as has been the effect of solid fumes on the soil.

Considerable success has been obtained by the use of the Cottrell system in eliminating fumes. There was a great deal of trouble early in the use of the Cottrell process because basic fumes could not be handled and it was found necessary to acidify them with a certain amount of sulphuric acid. This has been found to be considerably cheaper than the old baghouse method of separating fumes.

New Hydrochloric Acid Absorbers

S. L. Tyler presented a paper describing a new form of absorber for hydrochloric acid. In essence it consists of an elongated and flattened S-bend with a trough in the bottom so that the gas passes over a shallow pool of ever changing liquid. A certain amount of acid is obtained by inclining the roof of the chamber toward the center from which the condensed acid will drop. By joining two or three or four of these units together a very effective absorption system is obtained. It embodies nearly every advantageous principle in the absorption of gas by liquid. A great deal of interest was expressed by producers of HCl in this apparatus which is made of quartz. The paper is an important one and will be published in *Chemical and Metallurgical Engineering* within a few weeks.

H. S. Taylor read a paper on "The Manufacture of Hydrogen and Nitrogen for Synthetic Ammonia." He pointed out a very significant fact—that about 75 per cent of the publicity had been devoted to the actual production of synthetic ammonia, whereas nearly 75 per cent of the cost of the ammonia was tied up in the hydrogen and nitrogen production. Dr. Taylor summarized all the processes by which nitrogen and hydrogen are usually made on a commercial scale and pointed out the economic reasons why the various processes were unsuccessful or successful. Most of the gas is produced by the water gas process. This, as it has been worked out, is fairly efficient and will produce one volume of hydrogen for every 1½ volumes of water gas made.

That particular gas ratio is the crux of the whole problem. If this ratio is high, the cost goes up proportionately because more coal is used. Dr. Taylor expressed some hope that the steam-iron contact process which gives hydrogen of very great purity, would be developed and indicated that Richardson's work was suggestive that this was entirely possible. Electrolytic hydrogen as a competitor of either of these other processes would have to have very cheap power and a much better cell of very high amperage before it could be a legitimate competitor. Dr. Taylor felt that it would not be feasible to use byproduct hydrogen in ammonia synthesis since it was extremely likely that ammonia synthesis would have to be carried out in very large units to be utlimately successful and that any byproduct hydrogen would be a very small drop in the bucket in a large unit.

A paper on "Some Economic Aspects of Ammonia Oxidation" by G. B. Taylor was read by F. C. Zeisberg, his colleague. This paper appeared in *Chemical and Metallurgical Engineering* for June 28[2] and it will be unnecessary to abstract it further.

Another paper presented by H. K. Moore of the Brown Co. and read by G. A. Richter, discussed the production of hydrochloric acid by direct union of hydrogen and chlorine. The paper was presented in abstract only and was extremely suggestive of the possible use of this method. Mr. Richter announced that very little trouble was had in the combustion chamber and that no catalyst had been employed, as the union of hydrogen and chlorine was extremely rapid without any catalyst. As a matter of fact, for months at a time no one had gone near the combustion chamber. The gases were produced by electrolysis, the hydrochloric acid gas being absorbed as usual in absorption chains and tourills.

N. T. Bacon then read a paper on "Vapor Tension at Low Temperatures." This was a theoretical paper and aroused considerable controversy.

Dr. Haslam then read a paper by Evans and Whitman on "The Bleaching of Nitric Acid with Air." This paper was undertaken as a study in the Graduate School of the Massachusetts Institute of Technology at one of their co-operating plants and gives a quantitative answer to a number of factors which have long been known to operating chemists. The bleaching of nitric acid with air is not new but a quantitative study of it has never been published. This paper will appear in a subsequent issue of this magazine.

Tank Cars for Hydrochloric Acid and Chlorine

J. M. Rowland of the Hooker Chemical Co. after discussing the unsatisfactory tanks made from impregnated wood and the high maintenance cost of these tanks, described a steel storage tank lined with unvulcanized para rubber. The rubber is cemented to the steel with a friction fabric. This tank has been quite successful in transporting the high quality "Hooker White" acid. This was so successful that they decided to try it out in tank cars and now have nine tank cars of 35-ton capacity which have been giving service for the last four months. Some of them have given even longer service.

F. C. Zeisberg then read a paper on hard-rubber lined tank cars and described a tank which had been constructed of steel with a hard rubber shell, the shell being protected from the steel with a lining of soft unvulcanized rubber. They have found this tank very satisfactory and anticipate the use of long tank cars if the present satisfaction is continued. One of the principal advantages of this tank is that it can be very easily cleaned and used for different liquids. G. A. Richter mentioned also the use of rubber lining for resistance to chlorine.

J. L. K. Snyder and H. C. Wells of the Niagara Alkali Co., read a paper on the transportation of liquid chlorine. The specifications for the 1-ton drums on the 15-ton tank cars were elaborated and the advisability of insulation and safety valves rather than fusible plugs was discussed. The present specifications which require three fusible plugs which would blow out at a temperature of 150 deg. would allow the liquid chlorine to blow out of the tank whereas a safety valve would simply blow off the gaseous chlorine which was causing the excess pressure. Another point of the specifications discussed concerned the desirability of having a check valve to prevent loss in case the outside valves were sheared off. Finally, the destruction of a liquid chlorine pool was discussed and the addition of water and earth was recommended. Chlorine hydrate, which is

[2] *Chem. & Met. Eng.*, vol. 26, No. 26, June 28, 1922, p. 1211

LARKIN CO. PLANT FROM THE AIR

formed when water is added to liquid chlorine, gives off chlorine vapor at a very slow speed.

Max Mauran discussed a new unit tank car for chlorine. In this car he placed 15 1-ton containers on a permanent cradle with proper bracing. This kind of car, he believes, would permit the minimum rate of transportation allowed on a tank car and at the same time would avoid demurrage charges, since the drums could easily be swung from place. Then, too, it would not tax the consuming company with large storage of liquid chlorine.

Phosphoric Acid by a New Process of Treating Phosphate Rock

W. H. Waggaman discussed the advances which have been made at the Bureau of Soils in the production of phosphoric acid. This process avoids the use of sulphuric acid which seems to set a definite low limit on the price of phosphoric acid. If a process could be devised which would produce phosphoric acid cheaply its natural advantages over sulphuric acid would displace this acid for many processes. Among other things which would have to be done would be the elimination of the selection and washing of phosphate rock at the mine. This would cut down the expense of mining considerably. In the sulphuric acid process a product containing 16 per cent phosphoric acid is obtained, whereas in the furnace method a very much purer phosphoric acid results. The furnace method, so-called, consists in heating silica and phosphate rock with or without carbon. It was first suggested by a French engineer in 1867 and was patented in the United States in 1895. However, it is still in an investigation stage although one plant designed by one of the men formerly with the Bureau of Soils, is now in operation in Alabama. Only short runs have been made on the furnaces and estimates over a run of 20 hours would indicate something on the order of 2½ cents per unit P_2O_5 which compares reasonably favorably with present market prices. Both electric and open hearth furnaces have been used and the comparison is very much in favor of the open hearth process, for with power at $25 per hp.-year we could pay $23 per ton for fuel, which is, of course, far above any market price. The efficiency of the electric process is however, better and there is undoubtedly less radiation. But as phosphate mines and electric power do not exist closely together, it is more than likely that if this process develops commercially the open hearth process will be used.

This paper elicited a great deal of very interesting discussion. Mr. Marshall suggested that 2½ cents per unit P_2O_5 is not an advantageous price as far as this new process is concerned and Mr. Landis of the American Cyanamid Co. said that he felt that there was one problem which distinctly militated against the success of this process—the lack of satisfactory refractory. Is there any refractory in existence which would stand up under the replacement of phosphate by silica? Without such a refractory the process was bound to fail. Mr. Landis stated that without using any carbon and thus going through the phosphorus stage from phosphate rock, the American Cyanamid Co. had obtained a 75 per cent recovery simply by replacement of phosphate with silica. This materially reduces the necessity for cheap power.

The final paper of the meeting was presented by G. T. Walker and discussed the crystallization of tri-sodium phosphate. First he presented theoretical curves showing that the true tri-sodium phosphate actually existed in solutions as far as the solubility curves could be interpreted and then discussed at some length the apparatus made by the Swenson Evaporator Co. and designed by himself, in which tri-sodium phosphate was crystallized successfully. This consisted of a tank through which the crystals were conveyed by means of a large conveyor and which was cooled on the outside by a water-cooled jacket.[3]

It is perhaps not inappropriate before writing *finis* to the Niagara Falls meeting, to comment on the generosity of the Institute toward its guests. Many of them invariably express their gratitude at being allowed to participate so completely in the activities of the Institute. A society with such unusually high standards of membership is not ordinarily so generous. Let this be considered therefore as a vote of thanks on behalf of the guests to the Institute.

New French Mill to Make Paper From Grass

The French paper industry is gradually emerging from the crisis caused by the difficulty in obtaining raw material from abroad. Every effort is being made to discover new material with which to manufacture paper pulp. A new company has just been organized under the name of "L'Alfa," with a capital of 8,000,000 francs, according to a report to the Department of Commerce from Commercial Attaché Huntington, for the purpose of producing paper pulp from plants, and especially from esparto or alfa grass, which is found in great quantities in Algeria and Tunis. The main office is situated at 124 Rue de la Boetie, Paris.

The new company has leased part of the Sorgues powder factory, near Avignon, and expects to produce pulp within a year. Other experiments are being made with vine shoote and have apparently proved satisfactory. Another effort is being made to acclimatize the Canadian poplar tree in France.

The French shipping company Les Armateurs Français is organizing a special service for the transportation of chemical wood pulp from Finland to France. The first shipment of 1,556 metric tons of paper pulp has just been discharged at Nantes and Bordeaux, coming from Hango, Finland. France hitherto has depended upon foreign ships for such transportation.

American Society for Testing Materials

Pig Iron Specifications Criticised by Steel Foundrymen—Important Symposium on Impact Testing—Uncertain Whether All Metals Possess an Endurance Limit Against Fatigue—Silicon a Great Help in Making Sound Aluminum Alloy Castings

AFTER two years' absence, the American Society for Testing Materials returned to its "stamping grounds" at Atlantic City. Its meeting held during the week of June 26 was perhaps the best attended in its history and perhaps also the most comfortable—the Chalfonte-Haddon Hall hotels attending to their part admirably.

As is well known, most of the work of the Society is done in committee. The reports made to the open sessions cover only the points upon which substantial agreement has been reached, and very rarely indeed is any controversy excited. Perhaps this custom was partly responsible for the apathy with which a very large gathering of men received the important report of the Joint Committee on Sulphur in Rivet Steel.[1] Furthermore, the Committee itself declined to draw conclusions or discuss its published results, for reasons (not stated) which were said to justify its course. With such a stand taken by those who knew most about the tests, there was little left for others to do but hope that the Committee will speedily make known its mind on the effect of sulphur on rivet steel, thus erecting a target to shoot at.

Pig Iron Specifications

In refreshing contrast to this state of affairs, the Committee on Cast Iron was severely criticised in attempting to hold that its specifications for "Foundry Pig Iron" was suitable for steel foundries or malleable iron foundries. As a matter of fact, this specification specifies nothing much but allowable *variations* in chemical analysis (the actual analysis is supposed to be agreed upon for each individual lot according to the need of the foundryman or the supply at the blast furnace), and its method of sampling and inspection. This state of affairs was justified by saying that it would be impossible to specify chemical analysis for each style of casting, large or small, ranging from a washer to a hydraulic cylinder—composition must be adjusted by the foundryman to his molding, melting and pouring practice. On the other hand, it was pointed out that any clean pig of iron would conform to the specification. Steel foundrymen objected to purchasing pig with a phosphorus of 0.15 maximum; or with manganese varying plus or minus 0.20 per cent. These figures are called for in the specification, and any exception thereto would probably involve an increased price.

Fatigue of Metal

Professors Moore, Kommers and Jasper, of the University of Illinois, presented a short paper recounting some of the main findings of the Joint Investigation of the Fatigue of Metals.[2] There are three main indications that tough steel possesses a definite endurance limit. If the numerical values obtained at Urbana are plotted on cross-section paper or logarithmic paper there seems to be a definite change of direction at a certain stress, the line becoming horizontal beyond. L. E. Tuckerman of the Bureau of Standards replotted some of the results on log log paper and found even a more pronounced break in the curves. Second, if stress be plotted against rise in temperature caused thereby, a sharp change in direction occurs at approximately the same stress. Third, if a bar which has endured 100 million repetitions just below the endurance limit be immediately tested in tension, its ultimate strength will be found to be unchanged or even increased slightly.

D. J. McAdam, Jr., whose extensive tests on rotating cantilever beams were reported in *Chemical & Metallurgical Engineering* for Dec. 14, 1921, vol. 25, p. 1081, stated that he had recently completed a number of tests at rather high loads, causing quick failures. Combining these data with published tests on long-time runs on the same steels, and plotting the results on cross-section paper, a very smooth parabolic curve resulted, becoming almost horizontal for higher endurances. He still insists, however, that the data in his possession indicate that the curves possess an appreciable, though small inclination, and consequently fail to mark any definite endurance limit, below which that steel will never fail.

Commenting on this same point, Dr. Haakon Styri of the S. K. F. Research Laboratories remarked that one of their new testing machines induces reversed axial stresses in the specimen. The only run now available shows no break in continuity when the loads from 12,000 to 55,000 lb. per sq.in. are plotted against temperature rise, even though the temperature goes up very rapidly at the high loads.

Furthermore, R. L. Templin of the Aluminum Co. of America said that their extensive tests on aluminum and magnesium alloys indicate no such definite endurance limits as Dr. Moore finds for steel. Many of the SN curves show an arrest, but later the curve again changes in direction, becoming approximately parallel to that for heavier loads.

Analyzing the results of two independent investigations, Mr. Tuckerman noted that the only specimens in the two series capable of direct comparison were of ingot iron. The fatigue strengths at Annapolis were consistently lower, however, a fact which may be explainable by differences in severity of machining operations when preparing the specimens, which may induce internal stresses or even rather deep flaws glossed over by the final polish. Or it might be due to heat treatment: the Annapolis material was normalized, while that sent to Urbana was box annealed.

Prof. Moore emphasized that endurance tests were to be used in conjunction with other physical tests; even when short time tests were available, it would be continually necessary to operate fatigue tests out to hundreds of millions of reversals. Consequently it was

[1] Abstracted at length in *Chem. & Met. Eng.*, May 31, 1921, vol. 24, p. 1011, and 1019.

necessary to devise means whereby the alternations could be impressed at high speed. (Lacking endurance tests, it had already been demonstrated that a moderately close approximation for tough steels would be 45 per cent of the tensile strength or 250 times the Brinell hardness.) Endurance tests are naturally of prime importance to the builders of high speed machines, turbines or springs (with stops to prevent overload). Automobile manufacturers often prefer the Stanton repeated impact test: It is intermediate in severity between the alternating test and the Charpy, and very useful since motor parts are continually subjected to moderate but very seldom to overpowering shocks.

Non-Ferrous Metals and Alloys

Attached to the report of the Committee on Non-Ferrous Metals and Alloys was an appendix by John R. Freeman, Jr., of the Bureau of Standards on the physical properties of the 12 A. S. T. M. standard white metal bearing alloys. It was found that alloys made under commercial conditions have a slightly greater strength and hardness at room temperatures than similar alloys made under close laboratory control. When testing at 100 deg. C. these properties are reduced by approximately 50 per cent, and the order reversed. Cylindrical test specimens 1.5 x 1 in. are easier to handle and more reliable than those twice as long. Brinell hardness measured with a 10 mm. ball under 100 kg. load gives very slightly higher results than when tested under 500 kg. load.

Aluminum-copper-silicon alloys were discussed in a separate paper by E. H. Dix, Jr., and A. J. Lyon of the Army Air Service. In order to test the brittleness of various alloys when cooling in the mold, a "hot shortness" test was devised. It consisted of making a green sand casting of ½-in. test bars with enlarged end bosses. These bosses gripped pins held 12 in. apart by a heavy iron plate. Many popular aluminum compositions are not able to produce a sound bar when cast in such a way, but only one of the alloys noted in this report (85:6:9 Al:Cu:Si) cracked in this test. If these cold bars are pulled in a tension machine, they will show slightly higher strength than those cast without constraint. These results are really due to actual ductility just after solidification, since there is little difference in coefficient of expansion or in shrinkage in the new and old mixtures. Silicon should be 3 to 6 per cent, the lower limit being preferable if copper is added. Four per cent of the latter is recommended, especially when machinability is desired. Without copper, the alloys tear much the same as pure aluminum, and dull the tools very quickly. The recommended alloy can be cast around hard cores without danger of cracking, and the tendency to draw and shrink at joints between thick and thin sections is surprisingly small. Physical properties of two alloys at room temperature follow:

	94:6 Al:Si	93:3:4 Al:Si:Cu
Tensile strength	19,800 lb. per sq.in.	21,800 lb. per sq.in.
Elongation in 2 in.	4.2 per cent	2.1 per cent
Charpy impact	2.06 ft.lb.	2.13 ft.lb.
Scleroscope hardness	9.5	13.2
Brinell hardness (500 kg.)	37	55
Shrinkage	0.161 in. per ft.	0.164 in. per ft.
Coefficient of expansion	23.4×10^{-6}	24.1×10^{-6}
Specific gravity	2.63	2.71

Corrosion

Last year (*Chem. & Met. Eng.*, vol. 24, p. 1145) the Committee on Corrosion of Iron and Steel was able to report the definite superiority of copper bearing sheets when exposed to atmospheric corrosion in the Pittsburgh district. All the 22-gage sheets, both copper bearing and copper free sheets, have now completed their history with the exception of two heats of copper bearing bessemer steels, which have no failures at all. Some 16-gage copper free sheets are beginning to fail in the same order as noted in the lighter material; no 16-g. copper bearing sheet has yet been perforated. Exposure tests at Fort Sheridan, in open country, are beginning to develop failures in the light gage copper free sheets first to fail at Pittsburgh.

Another quick test for the amount of zinc on galvanized articles was reported by D. M. Strickland of the American Rolling Mill Co. If a 2¼ x 2¼ in. piece of the sheet is snipped off, immersed in 100 cc. of concentrated HCl and the rise in temperature noted by an accurate thermometer reading to 0.1 deg. C., the grains of zinc taken into solution (and for this size specimen, the ounces of zinc per sq.ft. of surface) equal the temperature rise multiplied by 0.168. The method is said to give quite accurate results, requires but a few seconds, and can be easily performed in the field. However, it gives no information on the uniformity of coating, or whether the same thickness of zinc is present on both sides of the sheet.

A very suggestive note, entitled "Preliminary Notes on Corrosion," by Prof. Wilder D. Bancroft of Cornell University, outlined some of the lines of research along which it is possible to approach the solution of the corrosion problem. He emphasized particularly the importance of studying the films which form in the atmosphere or other corroding media, films whose character influence subsequent action far more than that of the underlying metal. Calling attention again to the need of an accelerated test, he ventured the opinion that when it was found it would be a rapid electrochemical test.

In commenting on the latter point, F. N. Speller said that he had found a useful test for estimating expected corrosion in closed systems handling water. It consisted of measuring the oxygen extracted from solution while passing through a given length of the pipe or over a given surface. Many speakers emphasized the importance of the film action, and deplored the lack of information in this matter. George K. Elliott called attention to the fact that a high polish often produces an extremely resistant film, apparently by mechanical means. H. S. Rawdon pointed out that most of Prof. Bancroft's suggestions applied to pure metals or alloys of the solid solution type, while alloys containing more than one metallographic constituent would probably act far differently.

W. S. Calcott, of the du Pont Co., told of efforts they had made to translate laboratory experiments on corrosion to the operating department, when the latter was desirous of building a container for a certain liquid or vapor, for instance. It seemed that every problem was unique and no amount of work was able to express the results of various experiments in a simple formula until it was suggested that the corrosion action was really a compound action, consisting first of the *formation* of a reaction product, and second the *removal* of this product. Following this lead, it was found possible to develop an equation, say, for the rate of formation of oxide of aluminum by acetic acid. Another equation was constructed expressing the solubility of this oxide in acetic acid. Combining these two it was found possible to predict with a fair degree of accuracy the action of that acid on an aluminum container.

Impact Testing

Ten papers on Impact Testing occupied one evening's meeting, the whole subject being examined in considerable detail. Bound together the preprints total over 100 pages, and it is naturally impossible to abstract their contents adequately in a few lines. Each interested engineer will wish to study the pamphlet in detail.

H. L. Whittemore, of the Bureau of Standards, briefly sketched the historical development of the test and listed the literature. The earliest machines still survive in the falling tup used to test rails and axles.

D. J. McAdam, Jr., of the Naval Engineering Experiment Station, then described the dozen or more machines proposed and now in use (to some extent at least) for testing either notched or unnotched specimens in one of four ways: Tension, shear, as a simple beam, or as a cantilever. The author outlined published information indicating that the figures found for resilience of the metal will be substantially unaffected by considerable variations in the speed of the blow and weight of anvil, or small variations in the weight of the hammer—if that weight is accurately known. Theoretical considerations on the size and shape of the specimen and notch indicates that this is of major importance. Unnotched specimens under impact will develop crystalline or granular structures characteristic of metal broken with little plastic deformation only in the most brittle materials. A properly prepared specimen should show an outward region of fibrous fracture, underlain by a crystalline or granular area. In the toughest metal this may only be had if the notch ends in a curve of short radius.

The great difficulty in measuring the pressures, accelerations and forces involved in impact testing, where failure occurs within 0.0015 to 0.006 sec., was discussed by Messrs. C. E. Margerum, of the U. S. Naval Ordnance Plant, Armin Elmendorf, of the Haskelite Manufacturing Corp., H. F. Moore of the Univ. of Illinois, and E. B. Smith of the Bureau of Public Roads. On account of the great decellerations involved, the autographic recording instruments must be of minute mass and act directly—without gearing. Magnification must be subsequently done microscopically. After such a time-space curve is found, before the acceleration may be computed (and hence the force) its second derivative must be worked out by laborious computation or delicate instruments, a method giving ample opportunity for errors. Mr. Margerum therefore recommended the crusher gage commonly used to determine explosion pressures, where the pressure drives in a small plunger, shortening a tiny cylinder of copper.

In view of the fact that the tensile test is performed by static forces, while the impact test measures energy for almost instantaneous rupture, and in view of the just described difficulties of measuring the accelerations necessary to transform energy into force. Messrs. F. C. Langenburg and N. Richardson of Watertown Arsenal expressed the opinion that it is useless to expect a simple or constant relation between the indications of the two tests; it varies with the nature of the steel. They have experimented with steels which broke in static tension with an elongation across the notch of about 175 per cent, whereas under impact the elongation was only 30 per cent. Two distinct types of fractures naturally resulted, viz., fibrous and crystalline. In view of the fact, therefore, that tension and impact testing reveal two different properties of metal, the Watertown Arsenal now judges the acceptability of gun forgings by the Charpy machine regardless of the tensile results, having found that no gun jacket or tube possessing an impact value exceeding 6 ft.-lb. has ever ruptured in service from causes which cannot definitely be assigned to defective ammunition, excessive powder pressure, and such like.

C. L. Warwick, Secretary of the Society, reported that an extended questionnaire had developed the fact that much impact testing was being done in America to determine toughness in heat-treated metal and to control specified heat-treatment, to determine ductility, to study causes of failure, and for acceptance of materials to work under heavy shocks. In view of the wide variety of machines and bars being used, it seemed desirable to attempt to simplify existing practice, especially in the shape of bar and notch, so that comparable results might be obtained in different laboratories.

Busheled Merchant Bar Iron

W. M. Myers, of the Highland Iron and Steel Co., noted that about two-thirds of the "wrought iron" made in this country—in fact nearly all the merchant bars—is busheled scrap. Busheling consists in heating to a welding heat in a reverberatory furnace, miscellaneous iron, steel, or a mixture of iron and steel scrap cut into small pieces. After welding heat is reached, the pasty mass is balled up, removed from the furnace, squeezed and rolled exactly as is true wrought iron made from puddling pig. In fact, the process originated soon after cheap Bessemer steel entered the market, and many puddling mills started reworking scrap rather than go out of business.

Busheled merchant bar may be indistinguishable from wrought iron made by puddling by chemical analysis, and only with difficulty under the microscope if the scrap used contains no steel. As pointed out by James Aston, of the A. M. Byers Co., it involves a prohibitive cost to insure the use of nothing but good scrap, and since the nature of the metal is unchanged, busheled bar is no better than its raw materials. True wrought iron is a composite material, and both the metallic portions and its slag inclusions are essential ingredients. Slag in busheled bar is essentially an iron oxide, whereas slag in wrought iron is the reaction product from refining pig iron, i.e., phosphide and silicates of iron. If much steel is used in the busheling furnace, the fact may be indicated by chemical analysis, showing carbon and manganese greater than 0.10 per cent. The nick and break test is also apt to be more crystalline than fibrous.

Increased Requirements for Malleable Castings

Progress in the betterment of the iron used in malleable castings is recorded by the specifications of the American Society for Testing Materials. Specifications were originated in 1904 and no changes were made for eleven years. In 1915 the first revision was made. Four years later, in 1919, the requirements were materially increased. The tensile strength requirement was raised from 38,000 lb. per sq.in. to 45,000 lb. per sq.in. and the requirement for elongation was raised from 5 per cent in 2 in. to 7.5 per cent in 2 in. Malleable foundries have been working to these specifications for three years, and it has been decided that malleable iron could be made commercially with still better physical properties. Specifications were therefore revised at the recent meeting of the A.S.T.M., so that the required tensile strength is 50,000 lb. per sq.in. and the elongation 10 per cent in 2 in.

Chemists in Public Life

General Tendency of Chemists Is to Take Interest Only in Such Affairs as Concern Their Personal Welfare — A Survey Shows That Few Chemists Are Public Office Holders—Chemical Club Organizes Council to Promote Public Welfare—Midland, Mich., a City Run by Chemists

AN EDITORIAL SURVEY

ON MARCH 15 last we published an editorial about the part taken by chemists in public affairs which was merely another reminder of an opinion that we have held and mentioned at other times on divers occasions. In substance our contention was that the chemist is among the most essential of human factors in the development of civic and community welfare and advancement, and that we rarely hear of him in this respect. We held that as citizens chemists may contribute great and enduring services to the communities in which they live, and that, generally speaking, they do not come to the front and volunteer to contribute in the measure that lawyers do.

There are more lawyers in the country than are needed, and fewer chemists than might profitably be employed. True, there are many chemists looking for work and not finding it at the present moment, but that does not mean that work for them is lacking. There is work for them in abundance, but the people who direct affairs are ignorant in this respect, and they fail to see the need of chemistry in the very places where it is needed most.

BUSINESS OF CHEMISTS TO MAKE NEED OF CHEMISTRY KNOWN

Now it is the business of chemists to make these needs known, and they become known only when they are uttered as opinions by persons of eminence or in authority; by persons whose advice is sought and followed. This does not mean that they are to be spoken by someone in the public employ, whether elected or appointed; it means they must emanate from someone who has won the confidence of the community.

We thought we'd see whether we had guessed wrong or not, and we wrote to representative chemists in different parts of the country, asking each if there were in his section chemists who are participating in public activities. Were there any who held public or quasi-public office? Were there any who are prominent in public speaking or reform movements or any other phase of public welfare? We discovered from the replies we received that we had been wholly wrong in our opinion of the activities of chemists in regard to the general welfare in one single city, and that a small one of 5,500 inhabitants. And we hope soon to find ourselves in error in respect to one other. Before referring to these in particular, however, let us quote from a few of our other answers, some of which are less encouraging. Here is one:

"Chemists here are much like other human beings and are taking interest only in such affairs, public or private, as concern their personal welfare. They are heard in public only when they have an ax to grind. And the few who have axes to grind are the ones who are always ready to talk. . . . Personally I think we chemists should not talk in public about chemical affairs. Our unvarnished statements are too often dressed up to make interesting news items, and then we have to apologize."

That, if you please, about the members of a learned profession! If our correspondent had said, "Chemists are very like clerks in boot and shoe stores, or cigar stores, or like street railway conductors," the words that follow might have been convincing—if that is the kind of chemists they have in that region. At the same time it would have been manifestly unfair. When we remember that some of the most eminent savants in the country are neighbors of our correspondent, we feel that he has a wrong slant on the subject. We learn from him, however, that chemists are not active in public affairs in his region.

The following is from one of the smaller states devoted to agriculture rather than to industry:

"I am afraid there are no members in our section who are prominent office holders. We are mostly teachers, and, to some extent, investigators; and how in the world can such a man do his duty by his laboratories and have time to gain prominence in politics? I do know several chemists prominent in public affairs, but they are pretty poor chemists! The lawyer turns to public affairs and politics as naturally as a duck takes to the pond, and the way in which he has made himself known is oftentimes no cause for envy. It seems to me that laboratory men must in the nature of things be, to a considerable extent, recluses; but the results obtained by the craft as a whole are surely no cause for regret!"

CHEMISTS ARE CITIZENS WITH MORE THAN AVERAGE RESPONSIBILITIES

Of course the reference to chemists as craftsmen is a mere slip of the pen. We are firm believers in the teaching of sound laboratory craftsmanship, but how about the mind of the chemist? As a citizen he has the obligations of a citizen, which are, of course, no less than those of a cabinet-maker or pipe-fitter or any other craftsman. But in addition to this he has entered a profession on which rests the responsibility of seeking and finding the nature of things and of applying this knowledge to the advancement of human welfare. His professional preparation is supposed to have equipped him with the vision to see what is denied to others. Shall he then hold his peace when opportunity for helpfulness presents itself, lest he be misunderstood? He is one of the *illuminati* of the community in which he lives. Should he hide his light under a bushel?

Another letter tells us that the head of the department of chemistry of the local college is president of the Chamber of Commerce. That sounds right to us.

And the secretary of the local section of the A.C.S. is superintendent of the Presbyterian Sunday School, which also indicates merit. "Aside from these two public services," the writer says, "I do not believe any of the other chemists in this part of the state are affiliated in any way with public work outside their profession."

Still another names four gentlemen who have made many addresses before Kiwanis, Rotary and Women's clubs and high-school audiences, and says there are others who have done the same thing.

Chemists Active in University Towns

We learn that the head of the department of chemistry of a state university has achieved prominence in connection with chemical work for industrial companies (which is not what we were after) and that in Scottish Rite Masonry he has conferred no fewer than 15,000 32nd degrees. The one other chemist of the section has been an active organizer of chemical and other scientific societies, farmers' clubs, rural life betterment associations, and while never holding any elective public office, is very active in public speaking. He says, "The scientists are the men who actually have the goods, but they are the worst salesmen I have ever seen!"

In another state university one of the professors of chemistry has served for 15 years as a member of the Board of Education and is at present a member of the Board of Health. With one of his colleagues he is a member of the Kiwanis Club. Still another professor is prominent in giving addresses before various public organizations.

A letter from a city of from 150,000 to 200,000 inhabitants which is the center of a great chemical industry tells of one gentleman of the chemical profession who takes a rather active interest in industrial social relations and reform movements. Otherwise, so far as our correspondent knows, few or none of the chemists of the section "are prominent in public welfare work or in public speaking."

An interesting note in regard to this very city is that its greatest chemical industry has passed from the hands of its founders and organizers into those of a group of "investors" who, on obtaining control, dismantled research laboratories, discharged chemists and enjoyed a general and promiscuous chemical head- and heart-cracking party. The chemists remaining do not know whether they are afoot or ahorseback; most, if not all of them, punch the time clock and receive their instructions from a group of traders who are just such strangers to chemistry as they are to humility. The chemists have ceased to function as men of science, and have become a kind of indentured craftsmen. They are indentured because jobs are scarce. We should not expect much work for the general welfare from men who are broken in spirit.

Chicago Taking the Matter Up

From Chicago chemists we obtained a formal reply to the effect that a sub-committee of the local section had been appointed to take the matter up. We are informed, however, that on receipt of our letter, the members of the section, who are very live wires, said, "Well, what about it?" They appointed their committee, and discovered that one of their number was rather active in certain charitable enterprises, but that on the whole the members of the section were not playing a prominent part in public affairs. But the Chicago chemists are not broken in spirit, and we expect within a year or so to see them as active in municipal affairs as the members of the local branches of the American Medical Association or the Bar Association.

From another Middle Western source our correspondent writes that he knows of no one of their number "who is markedly active in public affairs, such as the lawyers of our community are." Then follows an argument to the effect that lawyers do not often make useful discoveries and inventions along scientific lines. Holy Writ is quoted, saying that no man can serve two masters, and that the man who is in the public eye is not of necessity a greater servant of humanity than the man who patiently and faithfully serves in the laboratory. "Of course," he continues, "there is nothing in this attitude which could be construed to mean that the chemist should not do his full duty as a citizen, taking part in the activities of his city and state whenever called upon. This should, however, be *as a citizen and not as a chemist.* In other words, citizenship should not recognize particular classes."

Obligation to the Community as Chemists

That is just where we take issue. Fifty to 60 per cent of the men and women of that community—unless its intelligence is clear above the average—have a mental age of not over 11 years. They do manual labor and can learn trades. They cannot co-ordinate or connect causes with effect. They can repeat political slogans, but they can't sense great principles. They're ready to say "Let's try" to anything that is proposed, which explains the amazing specimens of men who are elected to be mayors of various large cities. If chemists have no more mind than such morons, then they are not chemists at all; they are mere laboratory drudges. Where does professional obligation come in, we should like to know? The chemist must be able to use his head if he is a real one and not a mere laboratory laborer. That is part of his professional equipment, part of what he should have to offer. Chemistry determines pure water, knows paving and building materials, can take a city's list of materials needed and provide specifications that are sure to cut down taxes; can aid in warding off disease, and must be present in the organization of a health department or in sanitation; it touches public work on every side—and it is up to chemists to do the touching.

We must pass over a number of replies in which we learn of one or two chemists in whole districts who lecture occasionally in public or are engaged in university extension work or who "are members of the Rotary Club," etc. Even in so great a section as St. Louis the secretary does not recall any chemist who is interested to a great extent in public activities, although the value of chemists in civic work is recognized. We are under the impression that here at least two eminent chemists have been overlooked, Dr. Frerichs and Dr. Caspari, who, we believe, have contributed liberally in this respect. We have not heard from Cincinnati, but the great services as a citizen of Dr. John Uri Lloyd would call for comment, and so would, probably, that of Dr. Alfred Springer among others.

Philadelphia Has a List of Distinction

From Philadelphia we have a list of twenty names, and our correspondent is sure there are as many more of whom he does not have intimate knowledge. The list is one of great distinction.

The secretary of a numerous and live section tells us of one of their number who is member of a local school board, and of a second who, as city chemist, "has the privilege of examining many samples of police-captured 'hootch.'" He concludes by saying: "I really do not know of any chemist hereabout who is prominent in public affairs. Probably it is what you expected. Certainly it is one of our weaknesses."

From the foregoing it does appear as though chemists are addicted to the habits of the modest violet. As for those who are engaged in industries which are under the control of traders only, who hold that "anybody can make this stuff, but it takes genius to sell it," we cannot expect much. Their very profession is a badge of inferiority in such cases. Under long-continued control of this sort, it is men of the dray-horse type that settle down. When the day's work is over they want to rest. Imagination is a nuisance. They are excellent men; thoroughly sound and good, but not built for leadership, and those who, without the necessary qualifications, try to lead, and fail, are real nuisances. We merely wish to add the note that it does not require the quality of leadership to contribute.

But now let us turn to a couple of answers that give us real encouragement.

Tacoma Organizes Active Body to Co-operate in Civic Affairs

From Tacoma, Wash., we learn that the Olympic Chemical Club on April 11 last created an active body of six members to co-operate with other civic bodies in the upbuilding of the community. The committee consists of the head of a biological laboratory, a tar refiner, a gentleman who was formerly a dairy expert in the Municipal Health Department, the representative of the du Pont company, the local manager of a large analytical and assay laboratory of Seattle with branches at Portland, Ore., Tacoma, Wash., and Kobe, Japan, and the president of the club, who is manager of a nut butter concern.

It would be difficult for a layman to sense the value of the special lines of chemistry with which these gentlemen are familiar, but among the six members of the council there should be well represented the points of attack on civic problems from the various angles of chemistry. The council meets once a week at luncheon, and has already begun to carry out its duties in accordance with its charter, and is giving every evidence of filling a real need in the city.

The charter is so well drawn that we publish it herewith. It offers the best lead we can give as to how to organize.

The Olympic Chemical Club

Chemical Engineering Council for Public Welfare

The Chemical Engineering Council, hereafter called "The Council," shall be a permanent body of five members selected from among the membership of the Olympic Chemical Club for the purpose of promoting the general welfare of the community in matters pertaining to chemistry, and also to promote the welfare of the chemical profession.

The activities of the council shall be independent of the Olympic Chemical Club except that the members of the council shall be individually responsible to the club for carrying out the purposes of the council and maintaining the dignity of the profession at all times under penalty of impeachment as hereinafter set forth.

The details of organization and duties of the council shall be as follows:

Organization: The members shall be appointed by the president immediately, to serve for the term of the president. As soon as practical thereafter they shall meet and choose by any method they shall see fit necessary officers and shall adopt a system of bylaws, the same to be approved by the club. Vacancies in the council shall be filled by the president as soon as possible. The president of the club shall be a member of the council ex-officio.

Duties: The duties of the council shall be to promote the welfare of the community and the profession:

1. By aiding in the establishment of desirable new industries.
2. By assisting already established industries to devolop along sound and proper lines.
3. By leadership of the community toward better conditions in sanitation, water supply, food inspection, manufacturing and marketing conditions and any matters relating to health and safety as bearing upon and related to the science of chemistry.
4. By educating the public to the advantages of a better appreciation of chemistry and a larger use of professional chemists and chemical engineers.
5. By raising the professional ethics of chemists and chemical engineers.
6. By the exercise of constant vigilance to protect the public from false steps in matters related to chemistry, and from being victimized by ignorant or unscrupulous promoters in matters relating to chemistry.
7. By co-operating with other organizations and agencies in the upbuilding of the community, this co-operation to be limited, however, strictly to matters in which chemistry is involved.
8. By studying the industrial resources of the community and being prepared at any time to supply data to those seeking to establish or develop industries.

The council, however, is specifically directed to avoid, as far as possible, giving free consulting service, or encroaching upon the field of qualified experts. The work of the council is rather to promote public welfare by expanding the field in which professional chemists and chemical engineers can operate for a respectable remuneration. Nothing in this charter is to be construed to mean that free work of a consulting nature is to be done for anybody, except occasionally when it is thought that a strictly limited amount of such free work might be justified as advertising or as publicity directed toward the development of remunerative work.

The council shall submit a report of its activities to each regular meeting of the club.

Impeachment: Any member of the council may be impeached by the club for unprofessional conduct damaging to the council or the club. Such impeachment proceedings shall be conducted by the club with all due care and consideration for the rights of the accused.

The council has our best wishes, and we await with eagerness the reports of its progress.

Midland, Mich., Run by Chemists

We now come to a real little chemical city, which is Midland, Mich., with 5,500 inhabitants, of whom 55, or 1 per cent, are chemists. Note also, please, that its leading chemical industry was organized by a chemist who remains in control and that when hard times came along, instead of regarding its research laboratories as "dead wood" and cutting them out after the manner of some larger concerns under the leadership of bankers, the concern works all the harder to find what it can produce which is wanted.

The City Council is composed of eight aldermen and a mayor, and for 6 years past the mayor and three of the aldermen have been chemists.

One chemist is on the school board, ten are in the Chamber of Commerce, five are members of the Rotary Club, and sixteen, or 33 per cent, are in the Kiwanis Club. All reform movements and welfare organizations, together with most of the church activities in the city, are backed by a good number of chemists. Ten have been active in public speaking along lines in which chemistry touches the public interest. Four are especially considered as deserving attention, being inter-

ested respectively as member of the State Fair Board, director of Rotary Club, in philanthropy, as president of the board of control of Midland Community Center, as prominent in all reform movements, as president of the Midland County Welfare Association, president of Midland Americanization Society, secretary Kiwanis Club, and as health officer. Under the chemical health officer restaurants have been improved 100 per cent by strict enforcement of sanitation laws, and the milk situation has been brought up to a very high standard. But think of improving restaurants 100 per cent by a chemist! We've always maintained it could be done.

Midland is known in Michigan as "The Chemical City." It is small, but its chemical control has paved its streets, lighted it, provided for a filtration plant, and got things generally into shape.

Fifty-five chemists does not seem like a large number here in New York. We have one chemist who is president of the Citizens Union, but we think that if he had a special committee of fifty-five chemists and engineers in that body, keenly alive to the welfare of the city and earnest in their resolution, so far as the chemical and engineering aspects of public affairs were concerned they would be properly attended to. The practical politicians, the Hearst newspapers and Tammany Hall and a good part of the Republican County Committee undoubtedly would be kicking against the effrontery of "those theorists," but in the end we should have a better place to live in.

Legal Notes

By Wellington Gustin

Remedies of Seller on Breach of Contract

The remedies of a seller of goods where the buyer has breached his contract to buy are laid down by the United States Circuit Court of Appeals, Second Circuit, in an action brought by Isaac M. Simonin, trading as C. F. Simonin's Sons, against Sigmund Kranter. (Kranter vs. Simonin, 274 Fed., 791.)

The transaction out of which the suit arose appears to be: Simonin agreed on July 16, 1919, to sell and deliver to Kranter 1,000 bbl. of Ceylon grade coconut oil, not to contain over 7 per cent free fatty acid, at a price of 20c. per lb. net cash, without discount. The buyer agreed to furnish a 90-day confirmed bank credit for documents, payment to be made against an f.a.s. railroad bill of lading, Philadelphia weighmaster's weight certificate and certificate of analysis. By a supplemental agreement on Dec. 1, 1919, there was a substitution of "refined edible coconut oil at a price of 24c. per lb. to be made within one month of Dec. 1, 1919." In other respects the contract of July 16, 1919, was confirmed.

The seller alleged in his suit that on March 5, 1920, he delivered to the buyer 100 bbl. of refined edible coconut oil, and received payment according to the terms of the contract of Dec. 1, 1919; and again he delivered 136 bbl. of oil which buyer refused to accept or pay for. Further the complaint alleged that the seller was ready and willing to deliver, in accordance with the contract of Dec. 1, 1919, the remaining 900 bbl. and demanded shipping instructions, and so repeatedly notified the buyer, who, on each occasion, requested the seller not to ship but to hold the oil subject to his orders; and on May 21, 1920, the seller notified the buyer that he would no longer extend the time for delivery beyond May 21, 1920. The buyer failed to give shipping orders or instructions, or to furnish the confirmed bank credit, as required by the contract of Dec. 1, 1919, and for breach of the contract the seller asked damages of $15,000.

The buyer alleged that the bank credit for documents was waived by the mutual consent of the parties, and further that the seller delivered the balance of 900 bbl. and agreed to store them for the buyer, who agreed to pay for them from time to time as he removed them from the warehouse, and until their removal to pay interest on the purchase price, storage charges, etc., but later insisted on immediate delivery and payment.

Upon a trial the jury found the facts substantially as alleged by the seller. As to the law applying, the Court of Appeals says the seller had as remedies the choice of endeavoring to indemnify himself by storing or retaining the property for the buyer and then to sue him for the entire purchase price, or he could sell the property, acting as an agent for this purpose of the buyer, and recover the difference between the contract price and the price obtained on such result, or he could keep the property as his own and recover the difference between the market price at the time and place of delivery and the contract price. He could do this both under the common law and under the personal property law of New York State (Consolidated Laws, N. Y., chapter 41).

Seller Need Not Show Goods Were in Stock

Again, the court said where the buyer failed to give shipping instructions and to furnish a bank credit, as agreed, it was not necessary for the seller, in order to show readiness to deliver the oil, to establish that he had it in stock; he may have purchased it in the market and resold it to the buyer. The buyer breached the contract by his failure to give shipping instructions and to furnish the bank credit, which excused further performance by the seller, of whom was required only such readiness as was necessary to enable him to make delivery at the time fixed for delivery, such oil being obtainable in the market at the time fixed for delivery.

Use of Rotary Kiln in Making Magnesite Refractory Compound Not Invention

In the recent suit brought by Charles B. Stone against the American Refractories Co., plaintiff sought recovery for infringement of patent 792,822, issued June 20, 1905, to Davidson, for a process or method of making a refractory compound for furnace linings or similar purposes. The District Court dismissed plaintiff's bill, and he appealed. The U. S. Circuit Court of Appeals, Sixth Circuit, has affirmed the decree of the District Court. (274 Fed., 241.)

Claims 3 and 4 of the patent were sued upon. Claim 3 follows: "The process of making a refractory magnesite compound which consists in comminuting natural magnesite, silica and oxide of iron, mixing the ingredients in a dry state, burning the mixture to clinker and comminuting the clinker."

Claim 4 is the same as claim 3, except a rotary kiln is mentioned. Defendant contended claims were invalid and not infringed. The Court of Appeals found that as early as 1896 the most suitable material for making refractory furnace linings needed in certain steel

processes was a magnesite ore found in Austria. This was pulverized, heated to a high temperature, which caused it partly to fuse together in clinker form, and was then ground into a fine granular condition. It might be sold in this shape to the user, to be by him spread upon the floor of the furnace and fused into an unbroken lining, or it might be made up into bricks and used in that form. This ore contained magnesia, iron and silica, and it was commonly supposed that the iron was necessary as a flux for the magnesia, and that the silica was an undesirable element.

Davidson's substantial discovery, as the patent owner in suit contended, was that the silica played a useful part in the combination, in that it reduced the temperature necessary to frit the material. And the court says it may be conceded that this discovery, calling for a purposeful, instead of an incidental, presence of silica, would lend patentability to a claim for putting together by known processes the known ingredients of the natural material, if the necessary novelty existed.

Further the court found that several manufacturers, including the Harbison-Walker Co., had been engaged in making this class of material since long before the date of Davison's invention. About 10 years after the patent was issued this company altered its process, and the American Refractories Co., defendant herein, began to use the process of Harbison-Walker embodying this change. Upon this change the charge of infringement rests.

Was Inventive Step Involved?

In considering this change the court says if it did not involve an inventive step, so that defendant's present process is not patentably distinguishable from that which was used before Davison's invention, Davison can have no patent which can be construed broadly enough to support the charge of infringement and can at the same time be valid.

As far back as 1898 the Harbison-Walker Co., which had been using the Austrian magnesite for this purpose, found difficulty in obtaining this material. Thereupon it proceeded to import and use a Grecian magnesite ore, which was similar to the Austrian save for a deficiency in iron. This deficiency was supplied by adding iron ore, and then the mixture was pulverized, then moistened to make a thick paste. This was made up into small blocks or "dobies" and burned in kilns of the type used in burning bricks. By this process the carbonic acid gas was driven off and the material "dead-burned." It was then in fritted or clinker form and was ground and used as described above. The court assumed the Davison patent extended to the mixture of magnesite and silica, by using the raw material which naturally contained both, and found that it discloses nothing not previously in use by Harbison-Walker, except that Davison mixed his materials dry and burned them in a rotary kiln.

Steps in Court's Reasoning

Therefore the question was presented to the court whether in 1904, date of the application of Davison for his patent, it would have been invention to substitute in the Harbison-Walker process a dry mix and a rotary kiln for a wet mix and a stationary kiln. How the court solved this proposition is here set forth as a matter of information on how it arrives at judicial decisions. Was there a distinct advance in the art beyond what a skilled worker in the art could not do? One skilled in the art to whom this problem was presented would have before him his pulverized magnesite ore, containing silica and needing iron, and also his pulverized iron ore. It was said that he would know that these materials should be mixed as intimately and perfectly as possible and then burned to the fritting or clinker stage. He would know that the rotary kiln was an instrumentality in common use for simultaneous mixing and burning of material which was to be fused into a clinker form. It was then specially familiar in making portland cement. While the finished magnesite refractory and the finished cement are distinctly different products, it is not easy to point out any substantial distinction in the mixing, burning and fritting steps of making the one or the other.

Advantages of Rotary Kilns Well Understood

The substitution of the rotary kiln for the other method of burning, the court thought, was only the step which would have occurred to any one fairly familiar with this kind of work; and this belief was backed up by other patents and usages. The patents to Reid of 1874 and to Ransome of 1886 describe rotary kilns for burning pulverized gypsum, or lime, cement, etc., and specify the advantages of that device for accomplishing what Davison desired to accomplish. The Ransome patent especially points out that for this purpose the operator may take his choice between putting the material in blocks and burning in a stationary kiln, or pulverizing it and feeding it into a rotary kiln, and also points out that the ingredients, such as clay and chalk, may be mixed either wet or dry.

A patent to De Navarro in 1896 describes the distinct advantages of the rotary kiln for making portland cement, but points out that it contains the same ingredients which constitute the magnesite refractory—namely, silica, alumina, iron and magnesia. Though the proportions are very different, the process of mixing and burning is precisely that contemplated by Davison when he calls for a rotary kiln, said the court.

A patent to Krottnaurer in 1900 and one to Lossing in 1901 further describe the operation of rotary kilns to accomplish effective mixing and burning, not only to cement, but, in the latter patent, of earths and chemicals. That there are no such distinctions between burning magnesite and burning cement that the cement kiln would not be familiar to the magnesite worker, the court cited a British patent of 1902 to Kirkpatrick, where Kirkpatrick discusses the use of a rotary or any other suitable furnace or kiln in the manufacture of magnesite compositions for use in furnaces.

Substitution of Rotary Kiln Not Inventive Step

Now the court says putting these considerations with the fact that the use of the rotary kiln for burning magnesite was established in Europe, and that such European usage was known in this country, and with the testimony of experts as to the common knowledge of the rotary kiln and what it would do, it must find that it would not have been invention in 1904 to substitute this process of burning for the kiln burning which Harbison-Walker was using, in its then current method of manufacturing magnesite refractory materials. It follows that the patent cannot receive a construction broad enough to cover a continuation of the old Harbison-Walker method with only this change.

Therefore the Court of Appeals affirmed the decree, being against the claims of the complainant.

Thermal Considerations In Sulphuric Acid Concentration*

A Study of the Physical Properties of Sulphuric Acid Solutions With Curves for Determining the Heat Required for Concentration and the Thermal Efficiency of the Operation

By FRED C. ZEISBERG
Chemical Department, E. I. du Pont de Nemours & Co.

SULPHURIC ACID is universally concentrated by the application of heat. The first interest of the designer of apparatus to concentrate sulphuric acid must hence lie in the thermal properties of sulphuric acid. Several articles have been written on this subject[1] and one of them[2] at least has treated the subject very thoroughly and comprehensively. The results, however, are not most conveniently expressed, and the original article is not particularly accessible. This, then, must be the excuse for the present attempt to present an old subject from a somewhat different viewpoint.

Specific Heat

The first thermal property of sulphuric acid which interests us is its specific heat. Many determinations have been made[3] of this constant, in addition to those given in Landolt-Börnstein. The figures of Knietsch are out of line with those of other workers, while those of Pascal[3] seem the most probably correct, and are shown graphically in Fig. 1, by the full line. It will

Specific Heat
Per Cent H_2SO_4 in Solution

FIG. 1—SPECIFIC HEAT OF SULPHURIC ACID SOLUTIONS AT 20 DEG. C., AND AVERAGE BETWEEN 20 DEG. C. AND THE BOILING POINT

be noted that these are for 20 deg. C. As the temperature rises the specific heat increases slightly, but no extensive investigation of the change at various concentrations seems to have been made. Figures reported by de la Condamine[4] indicate that, if the increase of specific heat with the temperature is linear, the average specific heat of 100 per cent H_2SO_4 between 20 deg. C. and the boiling point is about 0.39. There has hence been drawn in Fig. 1 the dotted curve giving the probable value of the average specific heats between 20 deg. C. and the boiling point for all concentrations of H_2SO_4 solution. The values given by this dotted curve have been used in the calculation of the examples which follow.

Boiling Point

The next thermal property of sulphuric acid which interests us is the boiling point of various strength solutions. A number of investigators[5] have studied

this property, but the results of Burt's work appear the most trustworthy. In Fig. 2 the various data have been plotted, the curve being drawn with respect mostly to the points obtained by Burt and Ferguson. Here again it will be observed that Knietsch's results are out of line with those of other investigators. Values read from the curve have been used in the calculations which follow.

Partial Pressures of Vapors From Boiling Sulphuric Acid Solutions

Another thermal property which interests us is the composition of the vapor emitted by boiling sulphuric acid solutions. The literature appears to contain no definite figures, but numerous indefinite references such as that "boiling sulphuric acid solutions give off nothing but water vapor until 170 deg. C., equivalent to 72

per cent H_2SO_4, is reached.[4] The du Pont company several years ago made some rough determinations of these partial pressures[6] which are shown in Fig. 3.

Heat of Dilution

Still another thermal property which must be known is the heat of dilution of sulphuric acid. This has been investigated by a number of investigators,[7] the values obtained by Thomsen[8] having been selected for use

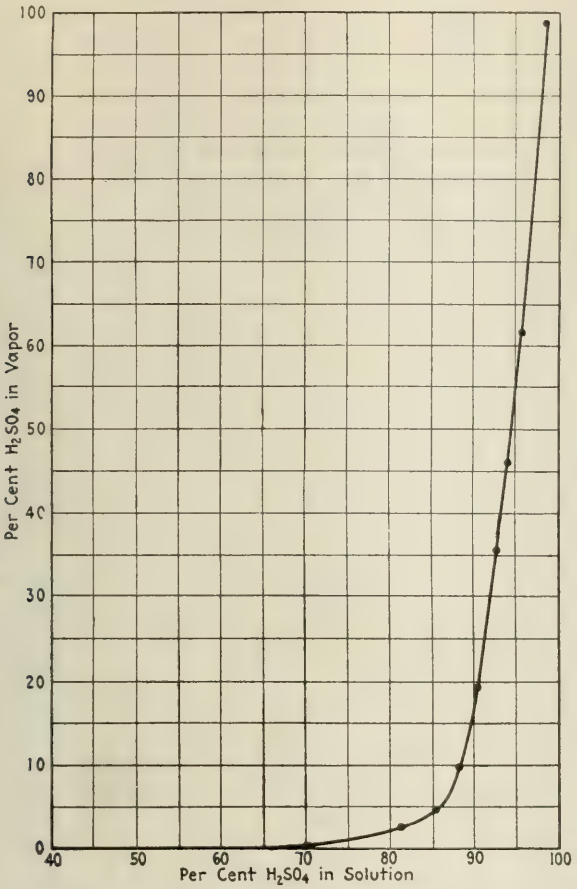

FIG. 3—COMPOSITION OF VAPORS IN EQUILIBRIUM WITH BOILING SULPHURIC ACID SOLUTIONS AT 760 MM.

herein. These values are shown graphically in Fig. 4, where both the curve obtained from the experimental results (full) and the one obtained by using the formula derived by Thomsen (dotted) are shown. This formula, it will be observed, agrees well with the experimentally determined points from about 20 per cent H_2SO_4 to 100 per cent. It will be obvious that the heat liberated in diluting from any given strength to any other strength may be read from the curve as the difference between the abcissas at those strengths.

Heat of Vaporization

The final property which interests us is the heat of vaporization of water. As is well known, this varies with the temperature, and Fig. 5 shows this variation graphically between 0 deg. C. and 350 deg. C., the values of Marks and Davis[9] having been used. In some cases, also, the heat of vaporization of H_2SO_4 itself

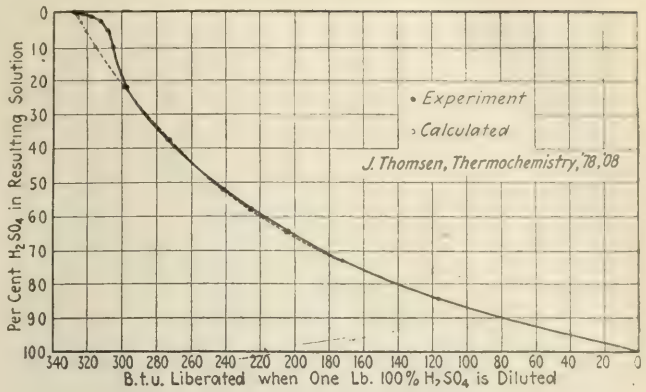

FIG. 4—HEAT OF DILUTION OF SULPHURIC ACID

may be of interest. This is 220 B.t.u. per lb. 100 per cent H_2SO_4.

Thermal Considerations in Concentration

If we now make the asumption that, in the concentration of a given quantity of sulphuric acid solution, it can be heated to the boiling point without the evaporation of any water until the boiling point is reached, the heat input up to the boiling point is made up solely of the sensible heat, which can be expressed by the equation

$$H_s = ws(t_b - t) \qquad (1)$$

in which H_s = sensible heat in B.t.u.
w = weight of acid in pounds.
s = specific heat of acid.
t_b = boiling point in deg. F.
t = original temperature.

After the boiling point is reached, continued input of heat accomplishes three things. Water is evaporated, hydrates of H_2SO_4 are decomposed, and the resulting more highly concentrated solution is raised to a new, higher boiling point. It is therefore perfectly

proper to regard the heat necessary after the boiling point has been reached as made up of three components, which, for convenience, can be called the heat of vaporization, H_v; the heat of dehydration, H_d; and the heat of maintained boiling H_b.

Analysis of the Heat Quantities Involved in the Concentrating Operation

The heat of vaporization is made up wholly, at the lower concentrations, of the heat of vaporization of water. At the higher concentrations there is added to it the heat of vaporization of the sulphuric acid carried along with the water—viz., 220 B.t.u. per lb. H_2SO_4. Since in the best designed sulphuric acid concentrating units all of this H_2SO_4 vapor but a small amount is recondensed under such conditions that the heat liberated in condensing is usefully applied, only the heat of vaporization of water will be taken into account, except as noted later.

The heat of dehydration is simply the heat of dilution reversed—that is, there must be put into the solution the same amount of heat, in order to break up hydrates, in concentrating from *a* per cent to *b* per cent, that would be given up by the dilution of the same quantity of H_2SO_4 from *b* per cent to *a* per cent.

The heat of maintained boiling is the summation of the increments of heat necessary to raise the acid to its new, continually higher, boiling points. It is sensible heat, evaluated as the product of a continually decreasing weight, temperature increments between continually increasing boiling points, and a continually decreasing specific heat.

Heat Required Shown Graphically

For the convenient use of designers and operators these various values have been calculated over a wide range of concentrations and shown graphically. Fig. 6 shows the sensible heat, H_s, required to bring 1 lb. of 100 lb. H_2SO_4 at any strength from any temperature to the boiling point. It has been calculated using the dotted curve of Fig. 1 and the full curve of Fig. 2.

Fig. 7 shows the heat of vaporization H_v, the heat of dehydration H_d, the heat of maintained boiling H_b, and the total heat H_t, the sum of H_v, H_d and H_b, for 1 lb. of 100 per cent H_2SO_4 concentrated from any strength to 98.5 per cent H_2SO_4. This latter figure has been selected because it is the highest strength of H_2SO_4 solution which can be reached by simple boiling at atmospheric pressure. When this concentration has been reached, both H_2SO_4 and H_2O are driven off from the solution by further boiling in a constant ratio to maintain this strength.

It is of course obvious that H_t can be obtained for 1 lb. of H_2SO_4 concentrated from any one strength to any other strength below 98.5 per cent, by simple subtraction.[10] The value of H_t thus obtained added to the value of H_s read directly from Fig. 6 then gives the total heat required theoretically to concentrate 1 lb. H_2SO_4 from any concentration and at any original temperature to any other concentration and boiling temperature at that concentration. This theoretical figure divided by the amount of heat actually used then gives the thermal efficiency of the process, which may be expressed as a percentage. If the amount of H_2SO_4 lost by evaporation is appreciable, as may be the case with simple concentration in open pans, then the theoretical figures read from the curves must be increased, as will be shown below.

[10] It is noteworthy that the curve H_t is practically a straight line from 67 per cent to 98.5 per cent H_2SO_4, and therefore that less than a 1 per cent error will be introduced by assuming that 0.1 B.t.u. is required per lb. of H_2SO_4 per per cent difference in that range.

Illustration of Use of Curves

An example or two will illustrate the method of using the foregoing curves and data. Suppose 60 deg. Bé. sulphuric acid at atmospheric temperature is being concentrated in open pans, with no fume recovery, to 66 deg. Bé., there being required 500 lb. coal, of 13,000 B.t.u. per lb., per ton of finished acid. The recovery is known to amount to 96 per cent. What is the thermal efficiency of the apparatus?

The per cent H_2SO_4 in 60 deg. Bé. acid is 77.7; in 66 deg. Bé. acid, 93.2 One ton of finished acid thus contains $2{,}000 \times 0.932 = 1{,}864$ lb. H_2SO_4, which required $500 \times 13{,}000 = 6{,}500{,}000$ B.t.u., or 3,487 B.t.u. per lb. H_2SO_4. One lb. H_2SO_4 in the finished acid corresponds to $1 \div 0.96 = 1.042$ lb. H_2SO_4 in the original acid. To heat 1.042 lb. H_2SO_4 as 77.7 per cent acid from atmospheric temperature, say, 20 deg. C., to boiling, requires, from Fig. 6, $194 \text{ B.t.u.} \times 1.042 = 202$ B.t.u. To concentrate 1 lb. H_2SO_4 from 77.7 per cent, and boiling temperature, to 93.2 per cent, requires, from Fig. 7, $465 - 122 = 343$ B.t.u. To concentrate 0.042 lb. H_2SO_4 from 77.7 per cent to 98.5 per cent—i.e., completely—requires, from Fig. 7, $465 \text{ B.t.u.} \times 0.042 = 20$ B.t.u., exclusive of the heat required to volatilize the H_2SO_4 itself. This would be $0.042 \times 220 = 9$ B.t.u. The total theoretical heat required is hence, per lb. finished H_2SO_4

	B.t.u.
Sensible heat, H_s	202
Total heat, H_t	343
Heat in H_2SO_4 lost by evaporation	9
Total heat of this lost H_2SO_4	20
Total theoretical	574
Actually used	3,487

Theoretical thermal efficiency $574 \div 3{,}487 = 16.5$ per cent.

Application to Surface Evaporator

In the case of the surface evaporator described by Mr. Gilchrist of the Chemical Construction Co.,[11] 11 gal. of fuel oil will concentrate 1 ton of 66 deg. Bé. acid, starting with 55 deg. Bé. acid at atmospheric temperature.

One ton of 66 deg. Bé. acid contains, as we have seen, 1,864 lb. H_2SO_4. Assuming the fuel oil has a thermal value of 18,000 B.t.u. per lb. and weighs 8 lb. per gal., there is used $18{,}000 \times 8 \times 11 = 1{,}584{,}000$ B.t.u., or 850 B.t.u. per lb. H_2SO_4.

The per cent H_2SO_4 in 55 deg. Bé. acid is 69.7 From Fig. 6, 193 B.t.u. is required to heat 1 lb. H_2SO_4 at this strength from 20 deg. C. to boiling, and from Fig. 7 the concentration from 69.7 to 93.2 per cent requires $663 - 122 = 541$ B.t.u. In this case the H_2SO_4 lost is negligible, therefore the total heat theoretically necessary is $193 + 541 = 734$ B.t.u. per lb. H_2SO_4. $734 \div 850 = 86.3$ per cent thermal efficiency.

Numerous other applications of the data contained in the various figures will readily suggest themselves to the reader.

[11] *Chem. & Met. Eng.*, vol. 26, p. 1159.

Edwin F. Ladd, Sole Chemist in U. S. Senate

AFTER 36 years of active work in a chemical laboratory, Dr. Edwin F. Ladd, the junior Senator from North Dakota, is having some difficulty in adjusting himself to the slow grinding of the legislative mill in Washington. For 20 years Dr. Ladd has been engaged in active hostilities in connection with the enforcement of North Dakota's laws pertaining to pure foods and materials. During most of that time he has had from one to three libel suits pending against him, to say nothing of injunctions and other efforts made to discourage him in his determination to obtain compliance with the laws of his state—a course in which he has had the active co-operation of most manufacturers and dealers.

While Dr. Ladd has good reason to know that obtaining national legislation is a long-drawn-out process, he is displaying in Washington the same perseverance that characterized his work in North Dakota. In addition to doing his part in the disposal of each day's legislative grist in the Senate, he is bringing to bear all the pressure in his power on his bills providing for such things as the adoption of the metric system, the compulsory working of patents and the setting up of purity standards for paints.

As Dr. Ladd is the only chemist in the Senate, he is being called upon more and more for advice and suggestion in connection with legislation dealing with chemical matters.

Dr. Ladd specialized in chemistry at the Somerset Academy at Athens, Me., and in the University of Maine, the two institutions in which he received his education. He was graduated from the latter institution in 1884 and immediately took a position as chemist for the New York State Experiment Station at Geneva, N. Y. He held that position until 1890, when he was called to the North Dakota Agricultural College to act in the dual capacity of professor of chemistry and chief chemist of the State Agricultural Experiment Station. Despite the fact that he has been in Washington constantly for 2 years, he continues to this day to hold title to both those positions. In 1915 he was elected president of the North Dakota Agricultural College. During the war he was Federal Food Administrator for his state. In that position he came in close contact with Herbert Hoover—a relationship which is being continued now that Mr. Hoover is a member of the Cabinet and Dr. Ladd a member of the Senate.

For many years Dr. Ladd has been an active member in the Association for the Advancement of Science, in the Society for the Promotion of Agricultural Science, in the Association of Official Agricultural Chemists, and in the Association of Dairy, Drug and Food Officials. He has served each of the latter two organizations as president. For many years he has maintained membership in the American Chemical Society and in the American Public Health Association.

Just at this time Senator Ladd, as a member of the Committee on Agriculture, is making an intensive study of the Muscle Shoals project. Regardless of the policy which the government may adopt in regard to the disposal of its properties there, Senator Ladd recognizes that this power project will be the center of a great chemical industry. He wants to see that great water power put to use at the earliest possible moment. He is perfectly willing for the government to go ahead and complete the dam and then dispose of the power in a businesslike manner to private consumers, since it is apparent that delays will intervene before an agreement can be reached for the disposal of the property to private interests.

Photo. copyright by Harris & Ewing

SENATOR EDWIN F. LADD

When Dr. Ladd came to Washington he thought the government should undertake the operation of the nitrate plants. His observations since, however, have convinced him that the government would not be efficient in the conduct of a chemical manufacturing plant and he believes the government plants should be leased to the highest bidder. He would like to see some one give the government more than Henry Ford has offered, but if no one is willing to make a better offer than Mr. Ford, he believes that Congress can exact certain practical limitations which will permit the country to have the advantages from that great natural resource.

In concluding this brief biography it is fair to point out that many of the legislative proposals of the distinguished senator from North Dakota are not in accord with our editorial policies. On several occasions in the past we have been forced to criticize rather severely Senator Ladd's stand on the soldier bonus. His abortive proposal to enact a specific and burdensome tax on banking institutions is not likely to receive serious consideration by Congress, but certainly to our way of thinking it marks a trend in a very dangerous direction. The potential power in the hands of the farm bloc is a problem viewed with apprehension by all who are mindful of the future legislative program of this country. The chemical industry at this time is vitally concerned with national legislative problems and it is to be hoped that Senator Edwin F. Ladd will make the most of his unique opportunity to champion the cause of chemistry in America.

Fiat Electric Steel Furnace

By Dr. Alfredo Stromboli
Turin, Italy

STUDIES on the new Fiat electric furnace, originated by Cav. Masera, manager of the steel foundry at the Fiat Works, Turin, were begun in 1916. In September, 1917, furnaces of the 5- and 6-ton types were put into operation. After improvements in details and in view of the most excellent results obtained, all the other steel furnaces in the foundry were replaced by this new type, six being constructed of 5 to 6 tons capacity, and a small one of 1½ tons capacity.

The Fiat furnace is a "fast" furnace and of large output, and is characterized by a perfectly tight roof maintained by means of a special economizer to be described. As will be seen from Fig. 5, the furnace consists of a cylindrical steel plate shell, properly reinforced, having a hemispherical bottom to which are attached two circular shoes of cast steel which permit the whole unit to be rotated in either direction by suitable hydraulic pistons. The shell and the refractory material with which it is lined have only two openings. One larger one serves for charging with the material and for removing the slag; the other, directly opposite to the first, for pouring.

Fig. 5 clearly shows heavy steel lugs attached to the sides of the casing into which fit the pintles of a lattice framework. This frame forms a sort of overhead bridge to the furnace and serves as a support for the entire upper mechanism, composed as a whole of the three economizers or electrode-carriers. Economizers constitute the characteristic and essential part of this furnace; they insure that the roof is hermetically sealed around the electrodes, and absolutely prevent any escape of gas or flame through the openings.

Fig. 2, on page 30, shows a section of the furnace, with an enlarged section of the Fiat economizer. It is composed of a cylindrical water pocket *A*, through which the electrode passes. A series of insulating rings are provided inside this cylinder, serving as guides to the electrode during its movement and keeping it from contact with the metallic wall. In the upper part, a circular layer of asbestos *C*, held in place by a metallic ring, is provided, acting as a packing ring in which may glide a sealing bell, formed of a cylinder of copper attached to a steel disk *B*, forming the cover. This cover has a hole in the center for the passage of the electrode and at the sides are two lugs with screw thread for the raising and lowering machanism. On this cover is located an insulating disk *E* and on this, by means of suitably insulated bolts, is secured the bronze clamp *F*, which grips the electrode. The latter, together with its clamp, is thus solidly connected with the bell, the purpose of which is to obtain a hermetic seal about the electrode by means of the packing rings on which it glides, thus absolutely preventing the circulation of air through the furnace.

All those parts form a complete unit which can be placed on the furnace and removed with great ease by means of a crane and without interrupting the operation of the furnace, as is shown in Fig. 5.

As a result of this hermetic seal, oxidation of the electrode is prevented, and electrode consumption is greatly reduced. Butt ends may be used to the last, as shown in Fig. 3, showing an electrode removed from a Fiat furnace after twenty-one heats of 5 tons each. The end piece was originally 1½ meters long, with a weight of 120 kg. After twenty-one pourings it was reduced to a length of 25 cm. with a weight of 20 kg., the consumption (counting all three electrodes) being

$$\frac{100 \times 3}{21 \times 5} = 2.85 \text{ kg. per ton.}$$

Since this seal prevents any and all circulation of air in the furnace, the atmosphere above the bath is kept constantly neutral. This circumstance enables us to dispense with the use of cast iron or other carbonizing agent in the charge. The cross-section of the electrodes remains unaltered; therefore the furnace may be speeded up, putting into it a large amount of energy, employing larger cables, electrodes of larger cross-section and transformers of greater capacity. The effects of the short-circuits which take place in the furnace are rendered negligible in practice by a well-proportioned transformer, by properly calculated distribution mains and by the adoption of a single conductor.

Fig. 4 represents the general arrangement of the electrical equipment of a Fiat furnace. It is apparent that it is a three-phase furnace with three electrodes

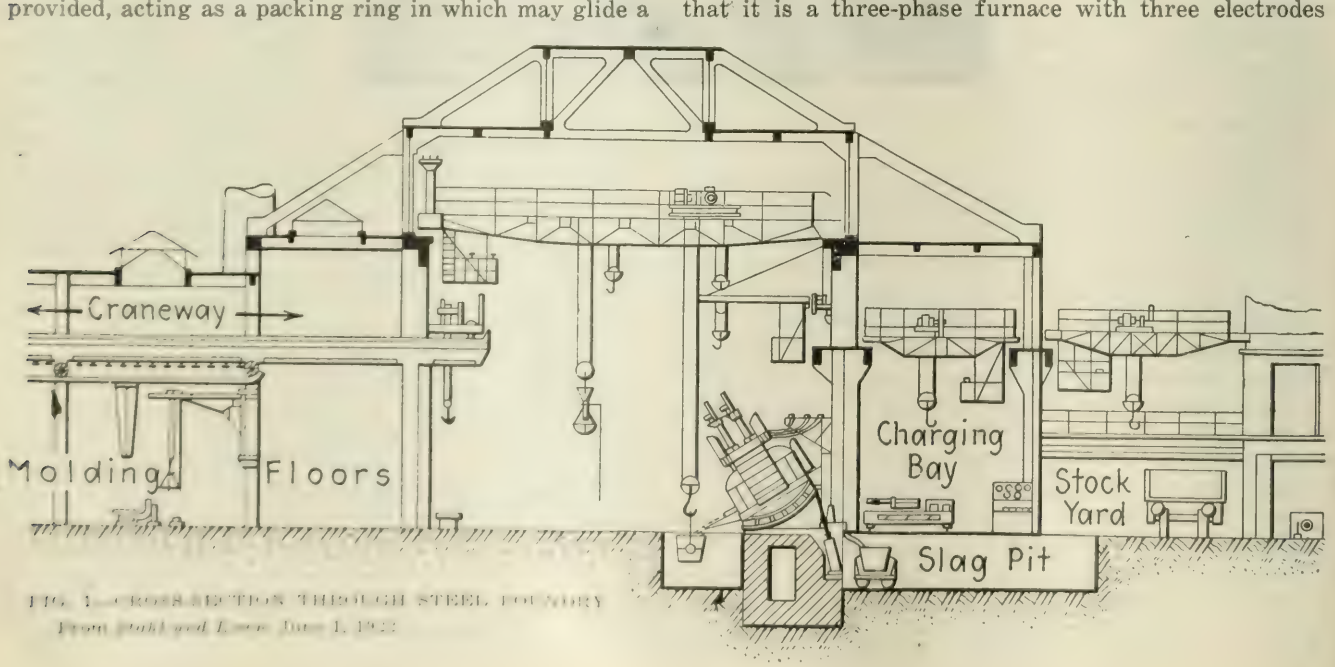

FIG. 1. CROSS-SECTION THROUGH STEEL FOUNDRY

High tension current (21,000 volts used at Turin works) is directly transformed to 120 or 75 volts by means of a static transformer, using oil and natural cooling. The whole electrical equipment has been calculated on the basis that a charge may be completed

FIG. 3—NEW ELECTRODES JOINED TO A BUTT

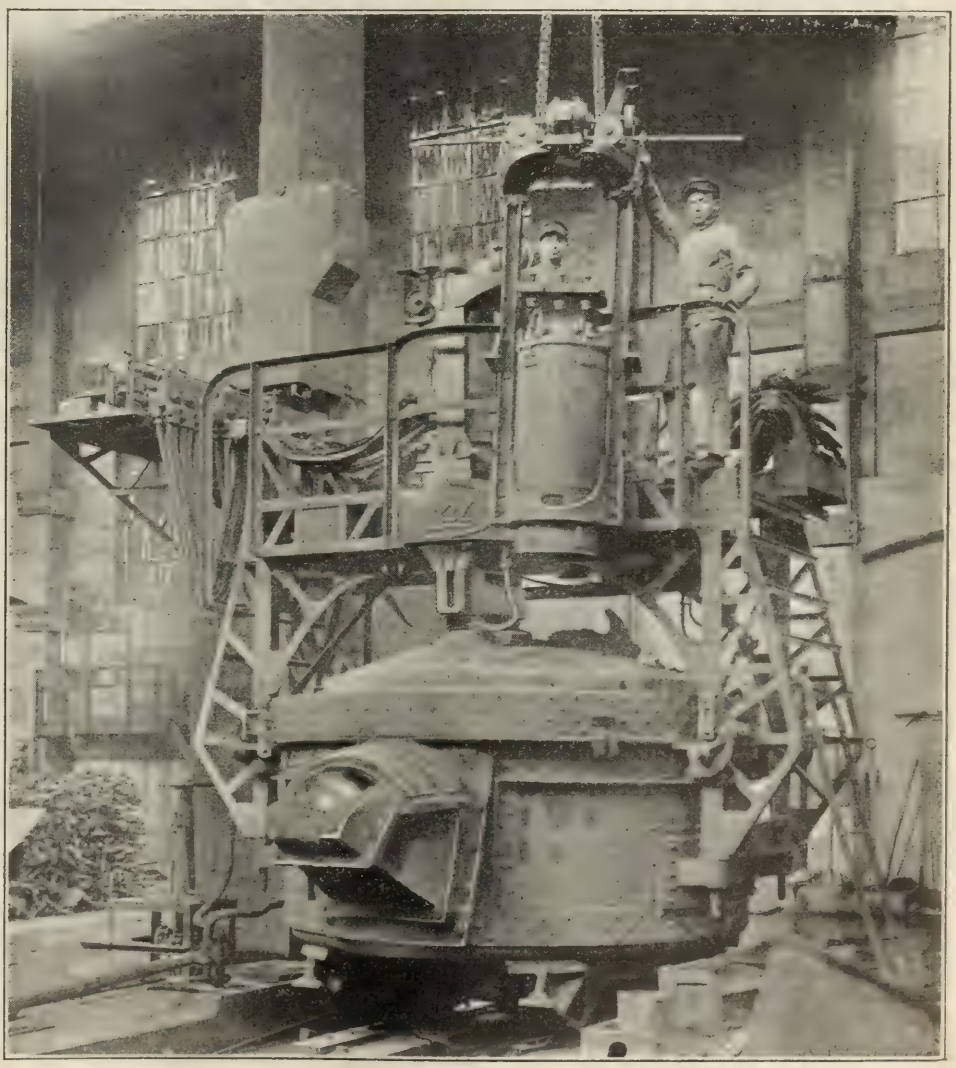

FIG. 5—PLACING AN ECONOMIZER ON A FIAT FURNACE

in 2 hours, 1½ hours of which is for melting and ½ hour for the refining period, wherein the temperature is carried to 1,750 deg. C. In fact, with the 5-ton Fiat furnace, the time required for a complete cycle is on an average 3 hours, filled exclusively by hand with scrap.

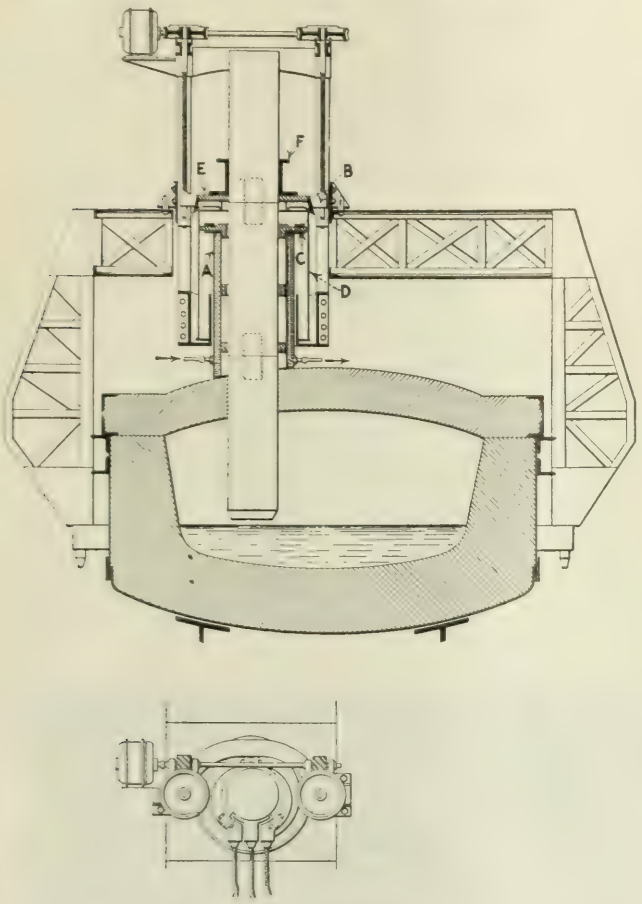

FIG. 2—DIAGRAM OF ECONOMIZER. (FURNACE LINES NOT DRAWN TO SCALE)

A power consumption test taken May 10, 1921, on furnace 6 (5 to 6 tons capacity) in the steel foundry of the Fiat works of Turin in the presence of several foreign metallurgical specialists gave the following results:

Beginning at 8:20 a.m., at the end of charge 56 and ending the next morning at the same hour with charge 65, exactly 24 hours was required for nine charges, including the time to fill by hand. Each charge consisted of 4,675 kg. of scrap without additions. The average time for each operation was 2.40 hours, in which the current was on 2.10 hours and ½ hour was used for charging.

Power consumption, measured by a watt-meter, totalled 25,100 kw.-hr. For 4,675 kg. × 9 × 0.94= 39,500 kg. of steel poured gives a consumption of less than 640 kw.-hr. per ton of steel cast.

How Much Steel in an Automobile?

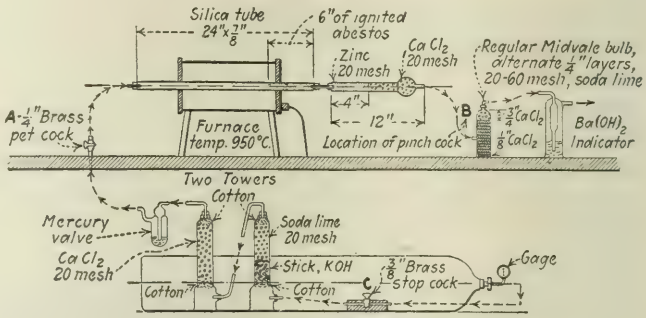
The burden the automobile industry places upon other industries is frequently overestimated. On an average, not much more than 1000 pounds of finished rolled steel is consumed per passenger automobile. Using round and conservatively high figures, taking 1200 pounds per passenger car the May production of passenger cars represented 125,000 gross tons of finished rolled steel, while the total production was about 2,350,000 gross tons. Automobiles, trucks, repairs and accessories hardly absorbed more than 7 per cent of the steel production last month.

Simple, Foolproof Carbon Combustion Apparatus

By William Kuebler

In the accompanying figure is shown a carbon combustion apparatus which has proved to be simple in operation and practically foolproof.

Determinations are made with full or one-half factor samples (20-mesh) using zirconia boats and 90-mesh R.R. alundum bed. A Davis-Bournonville gage on the oxygen tank is set so that the required rate of flow (200 to 250 bubbles per minute) is maintained. Once set, this gage is never touched until the tank is empty. When the apparatus is not in use, the supply of oxygen is shut off by means of stopcock *C*.



CARBON COMBUSTION APPARATUS

Having regulated the flow of gas, the pinch-cock *B* is closed, the stopper removed from tube and stop-cock *A* is closed. The boat with sample is then inserted in tube, tube closed and sample allowed to soak for 3 minutes. Meanwhile, the Midvale absorption bulb is weighed and connected. At end of 3 minutes open *A* and then pinch-cock *B*. Oxygen is allowed to flow for 7 minutes, this ordinarily being sufficient time for complete combustion. When oxygen first enters the tube and combines with the carbon and iron the flow is appreciably diminished, as will be shown by the indicator bottle. When the reaction is complete the flow of gas resumes its normal speed.

At the end of the 7 minutes remove the Midvale bulb, close pinch-cock *B*, remove stopper, close stop-cock *A* and remove boat. Immediately insert new sample, close tube and allow to soak the required 3 minutes while weighing bulb.

It has been the author's experience that the gage and a mercury valve give more consistent pressure than a water pressure tank and also eliminate the continual changing of the pre-purifying train due to moisture carried over with the oxygen. With the apparatus described, renewals of the pre-purifying train are made about every 6 months; of the zinc and calcium chloride tubes about every month. Renewals are governed by the number of determinations made and the behavior of standards run at the beginning, middle and end of each day's run.

The two towers shown supply five combustion trains, the division being made after the oxygen leaves the mercury valve. Arrows indicate tubing required and direction of current of oxygen. The rate of flow of oxygen is 200 to 250 bubbles per minute, which is sufficient if tubes, etc., are properly packed.

Synopsis of Recent Chemical & Metallurgical Literature

Dyes and Coal-Tar Chemicals in 1921

Tariff Information Series No. 25, recently published by the United States Tariff Commission, is a preliminary summary of the "Census of Dyes and Coal-Tar Chemicals, 1921," which has been prepared with the assistance of Warren N. Watson and C. R. DeLong for the use of the Senate Finance Committee. The report indicates that the total production of intermediates in 1921 by 107 different manufacturers was 70,899,912 lb., a decrease of 73 per cent in quantity from the 1920 output. The total sales in 1921 were 33,637,326 lb., valued at $8,483,463.

The number of intermediates reported in 1921 was 232, as compared with 236 in 1920. Of the total number reported in 1921, 49 were reported for the first time. The commission points out that the large decrease in the 1921 production of intermediates may be attributed to the following causes: (1) The loss of most of our export trade in dyes, (2) the large stocks carried over from the previous year, and (3) the general business depression. In general the intermediates used in producing those dyes consumed in the largest quantity show the most reductions.

Dyes and Other Finished Products

Dyes — The domestic production of dyes in 1921 by 74 manufacturers totaled 39,008,690 lb., a decrease of 56 per cent from that of 1920. The sales during 1921 totaled 47,513,762 lb., with a value of $39,283,956. The sales exceeded the production by 22 per cent, indicating that a part of the domestic consumption for that year was supplied from stocks carried over from the previous year's abnormal production. The average sales price of dyes for 1921 was 83c. per lb., compared with $1.08 for 1920 and $1.07 for 1919.

The production of dyes in 1921, grouped by classes according to method of application, is as follows: Acid dyes, 7,751,698 lb., or 19.87 per cent of the total production; basic dyes, 1,852,243 lb., or 4.75 per cent; direct cotton dyes, 6,787,634 lb., or 17.4 per cent; sulphur dyes, 10,239,255 lb., or 26.25 per cent; vat dyes, including indigo, 7,019,120 lb., or 17.99 per cent; the vat colors being divided as follows: Indigo, 6,673,968 lb. and other vats 345,152 lb.; mordant and chrome colors, 3,773,438 lb., or 9.67 per cent; lake and spirit soluble dyes, 697,444 lb., or 1.79 per cent; unclassified dyes, 887,858 lb., or 2.28 per cent.

Color Lakes—The total output by 43 firms of this class of pigments was 6,152,187 lb., compared with 10,983,538 lb., valued at $5,871,820 in 1920. Total sales of color lakes for 1921 amounted to 6,424,612 lb., valued at $2,863,189.

Photographic Chemicals — The production by 5 firms of these coal-tar chemicals used as photographic developers totaled, in 1921, 183,798 lb. compared with 440,759 lb. in 1920. Sales during 1921 amounted to 170,221 lb., valued at $248,041.

Medicinals—During 1921 conspicuous progress was made in the development of synthetic medicinals of coal-tar origin. The total production for 1921 was 1,545,917 lb., including a small quantity of disinfectants, the sales amounting to 1,876,246 lb., valued at $2,930,324. The 1920 production, including a considerable quantity of disinfectants, was 5,184,989 lb., valued at $5,726,776. Total production figures for 1920 and 1921 are, however, not strictly comparable, due to the large quantity of disinfectants of a relatively low value reported in 1920 and the small quantity of this group reported in 1921.

Perfumes and Flavors — The total output of flavors by 17 firms in 1921 was 901,245 lb., compared with 166,884 lb. in 1920. Sales for 1921 amounted to 933,662 lb., valued at $1,002,018. The production of perfumes by 15 firms in 1921 was 119,335 lb., compared with 99,740 lb. for the previous year. Sales in 1921 amounted to 119,691 lb., valued at $175,815.

Synthetic Phenolic Resins—These products are used as substitutes for amber in making pipestems and similar articles, electrical insulators, varnishes and lacquers. The 1921 production by three firms was 1,643,796 lb., compared with a production of 4,659,680 lb. during the previous year. Sales in 1921 amounted to 1,674,456 lb., valued at $1,352,166.

Synthetic Tanning Materials—The output of these products by four firms amounted to 1,902,597 lb. in 1921, compared with 3,142,861 ib. in 1920. The sales were 1,721,359 lb., valued at $141,005, during 1921.

Mechanical Handling of Superphosphate

In a recent issue of *Chemical Age* (London) George Frederick Zimmer presents a paper under this title which describes an installation for this purpose and built by S. S. Stott & Co., of Haslingden, England.

As should be well known, superphosphate is manufactured as follows: The ground phosphate rock and a certain amount of sulphuric acid are passed through a mixing machine which stands on a floor above the dens or cellars in which it must lie for some time to mature. After this mixing, the substance is permitted to run by gravity into one of the dens. Large wooden doors are provided for these dens, which are placed in position before they are filled, and when one of the dens is ready for discharging, the door is lifted away bodily, in modern plant, by a small overhead crane. Previous to the adoption of the mechanical handling devices which form the subject of this essay, the super-phosphate had to be cut from the pile in the dens by a gang of men with spades, shovels and wheelbarrows.

The mechanical excavator consists essentially of a carriage with flanged wheels which travels on a steel rail track reaching from end to end of a series of two, three or more dens. Superimposed upon this is a mild steel structure on a turntable. The excavator arm is located in such a way in a central position of the steel structure that it may be raised or lowered relative thereto as well as rotated therewith. With this provision the arm which carries the moving scrapers can be swung into the requisite position and made to enter any one of the dens (in this case only two).

The scraper arm is driven by a 7-b.h.p. electro-motor, supported on the inner end of the arm—i.e., within the steel structure—and the motor is raised or lowered vertically with the scraper arm. The scraper proper is an endless running chain conveyor fitted alternately with stirrers and prongs. The cantilevered arm is suspended by a cast-iron yoke from steel wire ropes and counterbalanced by a weight.

When a den is to be discharged, the door is removed by a small overhead crane; the scraper arm is then raised to its highest position, in which it is introduced into the den and started to work, cutting a slice of superphosphate a few inches deep from the top of the bed; when the material is thus raked out, it falls upon the tray conveyor in front of the dens. When the excavator has traveled laterally across the top of the deposit reaching the other wall, an automatic gear lowers the scraper arm a few inches and simultaneously reverses the motion of the machine, thus commencing another cut of the bed on its return travel. This operation is repeated until the den is empty.

It will be noticed that during these reciprocating journeys from side to side of the den the excavator travels alternately in the same and then in the reverse direction with the tray conveyor. When the former is the case the amount of superphosphate deposited into each individual tray of the conveyor is much greater than when the excavator travels in the reverse direction of the conveyor. It was, therefore, necessary to construct the tray conveyor for a maximum capacity, and it is, therefore, 24 in. wide.

On reaching the end of the tray conveyor the superphosphate is delivered to the boot of an inclined bucket elevator, 37 ft. long from center to center, with malleable cast-iron buckets 18 in. wide, by which it is lifted and delivered into tip wagons on the floor above the dens for conveyance on an overhead track to an adjoining shed to be stored.

The conveyor is 41 ft. 6 in. long from center to center, and 24 in. wide; it is carried on a single strand of No. 600 Ley's bushed chain, each tray having a mild steel axle with two cast-iron trodwheels. The inclined elevator carries buckets at a pitch of 18 in. which are

attached to a double strand of the same chain as the conveyor.

The electro-motor is one of 30 hp., and drives the mixer, the drag chain for traveling the excavator, as well as providing power for the tray conveyor and bucket elevator.

The two dens are 16 ft. wide each, they have a depth of 17 ft. from the open front to the back wall and are 18 ft. high from floor to ceiling. Their capacity is 50 tons each, which quantity can be removed by the plant in 2 hours. A very considerable saving of onerous labor is therefore effected by this installation, as almost the entire manual labor is deleted, with the exception of attendance.

Structure of Pearlite

A paper entitled "Inner Structure of the Pearlite Grain" was presented before the May, 1922, meeting of the Iron and Steel Institute by Colonel N. T. Belaiew. He assumes that in well-made steels, very slowly cooled through the transformation range, the austenite breaks up into parallel flat films of ferrite and cementite, the former about three times as thick as the latter. Under these circumstances all ferrite films are thought to be of substantially the same thickness in the same grain and in fact throughout the same piece of steel.

Granting these premises, the apparent distances between the fine workings in well-developed pearlite will depend upon the angle which the polishing plane makes with the crystalline plates comprising the grain. The finest, closest markings will represent the actual thickness of the plates, for that grain was cut normal to the structure. As the angle becomes less the pearlite appears coarser and coarser. As the angle between the films and plane of polish becomes less than 10 deg. the intersections become frayed during cutting or polishing so that the appearance of lamination vanishes.

Measurements on several steels showed that cementite lamellæ in "five lamellar and sorbitic" steel is about 25$\mu\mu$ thick. "Exceptionally coarse" pearlite has cementite plates about 300$\mu\mu$ thick. In both cases their adjacent ferrite plates are assumed to be three times as thick.

Cyanide From Calcium Cyanamide

Horace Freeman, in an interesting paper recently presented before the Chemists' Committee, Advisory Research Council in Ottawa, and published in the June issue of *Canadian Chemistry and Metallurgy*, describes the early development and later successful production of sodium cyanide from lime nitrogen (crude calcium cyanamide). The process now used at Niagara is carried out by mixing raw lime nitrogen, rock salt and calcium carbide. This mixture is fed into large crucible-shaped electric furnaces, lined with carbon blocks. The furnaces are wide at the top and constricted at the bottom, having a single centrally hung graphite electrode 12 in. in diameter, the lower end of which is about 12 in. from the bottom of the crucible. This is also electrically connected. Single-phase current is used. A tap hole leads from the extreme bottom of the crucible and is closed with an iron plug on a long rod.

The furnace is filled with raw materials to a depth of several feet, and as no foaming takes place and all heat is generated at the bottom, no gases or flames escape from the top of the furnace and the intense heat of the operation is not apparent until the furnace is tapped. A very high current density is employed so that the heating of the mixture between the electrode and the bottom of the furnace is extremely rapid. As the mixture melts the conductivity rapidly increases and the current correspondingly increases. When the current reaches a certain fixed upper limit, corresponding to a known temperature of the fused cyanide inside the furnace, the tap hole is opened by withdrawing the plug. The fused material flows down a conduit to a sump, from which it is rapidly taken up and cooled from its temperature of over 1,300 deg. C. by means of a rotating steel wheel having continuous water circulation through hollow shaft and rim. The temperature is reduced to a black heat by this means in a few seconds. The material is removed in the form of thin flakes by a scraper and packed in sheet iron or steel drums.

In the earlier experiments which Mr. Freeman had conducted at Vancouver, approximately 90 parts of salt were used with 100 parts of lime nitrogen. The efficiency of nitrogen formation to cyanide was 94 per cent and the product contained up to 36 per cent of cyanide calculated as sodium cyanide.

After a batch of material is tapped from the furnace the superimposed layer of partly heated material falls down and takes its place. The electrical contact is not broken, so that the temperature again rapidly mounts and the operation is repeated. The furnace is thus kept under complete electrical and heat control, and is mechanically operated except for the necessary attendant for tapping, who watches the ammeter.

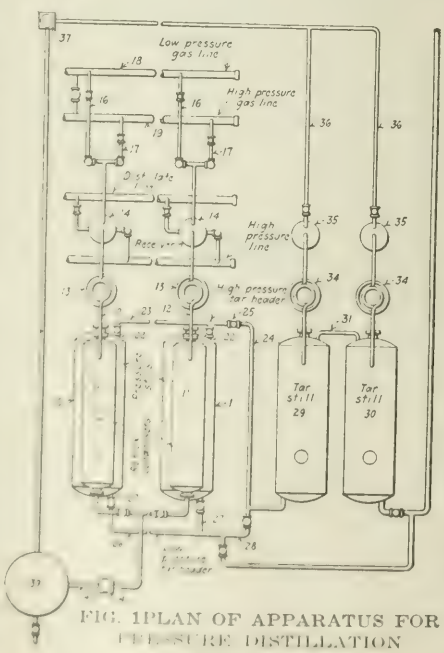


FIG. 1—PLAN OF APPARATUS FOR PRESSURE DISTILLATION OF PETROLEUM

Recent Chemical & Metallurgical Patents

Pressure Distillation of Petroleum.—A continuous process of distilling petroleum oils under pressure is the subject of a patent by Edgar M. Clark, assignor to the Standard Oil Co. of New York. Briefly the process consists in operating simultaneously a battery of pressure stills and separately condensing and collecting the distillate of each still. The withdrawn condensate is taken off through a common drawoff line and distilled in an ordinary tar still. The product of this distillation is returned to the pressure stills and is supplemented by a sufficient quantity of fresh oil to maintain a constant level in each still. A feature of the pressure stills is that they are constructed so that a uniform pressure is maintained in all stills by permitting a free interflow of uncondensed distillation products between the stills.

The apparatus is shown in plan in the figure. The battery of stills, which in general would consist of six to twenty stills arranged in a row, is indicated in the figure by the two end stills 1 and 10. Each is equipped with its individual reflux fractionating condenser 11, from which the vapor line 12 of each still is led to a water-cooled condenser 13 and thence to a receiving drum 14 for the distillate. Each receiving drum is connected by branching valved pipes, 16 and 17, to low- and high-pressure gas mains designated 18 and 19.

At a point below the normal liquid level in each still, the particular point being determined by the form of still employed, there is a valved high-pressure tar draw-off as indicated at 22 on the drawing. These tar draw-off lines from the several stills are manifolded to a common high-pressure tar header 23. At the end of the battery this high-pressure tar header discharges into a low-pressure tar line 24 through a pressure release and control valve 25. A separate low-pressure tar header designated 26 extends along the battery and is provided with valve connections 27 for each still, these low-pressure tar connections being tapped into the lowest point in the still, so that the latter may be completely emptied through them. The low-pressure tar header 26 communicates with the tar line 24 through a valve connection 28.

The tar line 24 discharges into a continuous tar still 29. For continuous operation it is often preferable to have a second tar still 30 connected with

the first by means of the overflow connection 31. Each tar still is equipped with its separate condenser 34 and receiver 35. From the receivers, distillate lines 36 lead to a tar distillate pump 37, which discharges by the line 38 into the feed-stock tank 39. Into the latter there is connected a feed line 40 through a pressure feed pump 41.

In the present discussion it is not possible to include the details of operation, for which the reader should consult the original specification. In this connection, however, the following statement of the patentee is of sufficient interest to be quoted.

"I have found that by continuously withdrawing a portion of the material under treatment from the pressure stills and continuously feeding a sufficient quantity of fresh stock to maintain a constant level therein, it is possible to prolong the continuous period of operation of the stills to such an extent that the output of light distillate from the equipment is substantially increased. I prefer to operate by charging each still into the battery initially and running off by the batch method—that is, without either feeding or withdrawing tar—approximately 20 per cent of the contents of the still before putting the still into communication with the high-pressure tar header and beginning the feed. I have found it easily possible to operate stills in this manner continuously for a week at a time without interrupting the pressure process for the purpose of cleaning the stills." (1,410,797; March 28, 1922.)

Recovery of Tungsten Trioxide From Tungsten Ores.—Tungsten ores are first calcined with chloride or chlorate of an alkali or alkaline earth at bright red heat. After pulverization the mass is treated with mineral acid and the impurities separated from the residue. Ammonia is then added, again separated and the ammonia driven off. Calcination at red heat leaves pure tungsten trioxide. (1,410,584, Simon Lubowsky, assignor to Metal & Thermit Corp.; March 28, 1922.)

Recovery and Elimination of Waste Sulphur Gases.—Twelve claims, all bearing on the purification of sulphur-bearing gases and concentration of their sulphur content, are made by Melville F. Coobaugh, of Golden, Colo. The process is based upon the ready absorption of SO_3 by iron oxide, Fe_2O_3, the oxidation of SO_2 to SO_3, by oxygen in the presence of Fe_2O_3. Both these reactions take place at about 450 deg. C. The ferric sulphate so formed can then be heated out of contact with air at temperatures around 700 deg. C., when it gives up its SO_3 in concentrated form. This will have application in metallurgical work where a minimum content of sulphur in exit gases is required by law. It also gives an opportunity to recover in usable form the large quantities of waste sulphur gases. (1,412,452; April 11, 1922.)

Gas Producer.—William B. Chapman, of Mount Vernon, Ohio, has patented a gas producer in which the operations of feeding the fuel, spreading the fuel, agitating the top surface of the fuel and removing the ash are performed continuously, automatically and in synchronism with one another. It is claimed that by this means the gas making can be scientifically regulated. This work is performed in this producer without moving the walls, top, ash-pan or other heavy and ponderous parts. It is claimed for this producer that the rate of fuel feeding, the thickness of the firebed and other conditions can be automatically regulated depending on the quality of fuel used and the rate of gasification desired. (1,412,921; April 18, 1922.)

Manufacture of Lithopone.—Formerly lithopone has been "muffled" in horizontal muffles, where poor control and uneven product result. Messrs. Singmaster and Breyer have passed the crude lithopone (zinc sulphide and barium sulphate mixture) through a vertical muffle 10 in. in diameter and 25 ft. long of wrought iron externally heated. In this apparatus the lithopone is first dried in the upper part of the tube and all the entrained air removed by the heat before it reaches the muffling zone. The tube dicharges directly into water. Continuous controlled operation is possible. They found the ratio of diameter to length very important, larger diameter giving uneven product. (1,411,696, Singmaster & Breyer, for New Jersey Zinc Co.; April 4, 1922.)

Vegetable Oil Extraction.—Hermann Bollmann, of Hamburg, has patented the application of the counter-current principle to the solvent extraction of oleagenous materials. The raw material is separated into batches and placed in receptacles provided with sievelike bottoms and open at the top. These are placed in the usual closed chamber in one direction and the solvent is caused to travel freely in the opposite direction consecutively through all receptacles, whereby the fat content of the solvent is progressively increased. This has the advantage of enabling loss of solvent to be avoided more efficiently and the passage through the material under extraction to be effected within the closed chamber from which the solvent vapors may be recovered and after condensation may again be utilized. (1,411,154; March 28, 1922.)

Manufacture of Soap — A quickly soluble white soap for laundry or toilet purposes is claimed to be made by a method which comprises disseminating a multitude of air bubbles throughout the soap while it is in a molten viscous condition and then diminishing the pressure under which the aeration took place so as to expand the air bubbles within the mass of soap. The puffed mass thus produced is permitted to cool and any excess moisture present is driven off so as to bring the product to the desired degree of dryness. (1,414,015, Truman, M. Godfrey, assignor to N. K. Fairbank Co. April 25, 1922.)

Book Reviews

ELEMENTARY CHEMICAL MICROSCOPY. By *Emile Monnin Chamot*. Second edition. New York: John Wiley & Sons, Inc. 479 pages, illustrated. Price $4.25.

This is a college text book on the use of the microscope in chemistry. The first part of the book contains descriptions of microscopes and accessories. This is followed by an explanation of microchemical technique, and finally by a detailed description of chemical reactions suitable for identifying the common elements under the microscope.

The author claims that microchemical methods have an enormous advantage over those of ordinary qualitative analysis in the saving of time, labor and material, as well as in the increased sensitiveness of the tests. In one of his lectures he illustrated the speed and sensitiveness of microchemical methods by describing the analysis of an antique coin. The edge of this coin was rubbed on a frosted glass plate, leaving a small mark. Part of the material in this mark was dissolved in a drop of acid. This drop was then split up into parts to which reagents were added, the reactions being observed under the microscope. In this way the composition of the coin was determined, the whole analysis requiring only twenty minutes.

The apparatus described in this book comprises chemical, metallurgical, petrographical, micrometer and ultramicroscopes and accessories. Elementary instructions are given for the use of each instrument. Critical comparisons are made of instruments designed for the same purpose, which makes the book valuable to refer to before buying microscopic equipment.

The most fascinating part of this book deals with microchemical technique. The author uses a microscope slide for a work bench. On this he places his microscopic fragments and drops of reagents, and performs the usual manipulations of qualitative analysis, such as solution, decantation, filtration, distillation and sublimation. In addition to chemical tests he uses melting points, refractive indices and polarized light phenomena in identifying microscopic materials and therefore devotes several chapters of his book to the description of these methods.

Following the explanation of microchemical technique is a detailed account of tests for each element. These tests differ from those of ordinary qualitative analysis in that they depend on the separation of crystals from relatively concentrated solutions, and afterwards identifying these crystals from their form, color and optical properties. It frequently happens that one reagent causes the separation of crystals characteristic of several elements at the same time. Each element can then be identified from its characteristic crystal

and this naturally results in a great saving of time and labor.

The book is thoroughly readable and authoritative in its field. After studying it under a figurative microscope the reviewer can only report that the examination merely corroborates the expectations that were aroused by the first glance at the title page which revealed the author's name. Dr. Chamot's work is worthy of his high position in his particular field.

OLIVER E. CONKLIN.

OIL SHALES. By *H. B. Cronshaw*, B.A., Ph.D., A.R.S.M. 80 pp., with map. London: John Murray, Albemarle St., W. Price 5s.

This small book forms a welcome and useful addition to the series of Imperial Institute Monographs on Mineral Resources, With Special Reference to the British Empire. A general account of the occurrence of oil shales throughout the world is condensed from the literature in a minimum of space. The selection of material is perhaps as judicious as possible, although, like any compilation, the work reflects here and there the inaccuracies of its sources. For example, we learn on page 6 that open-cut mining will probably prevail in the United States.

The first chapter is devoted to a general discussion of the character of oil shale and its utilization. The description of American distillation has, curiously enough, been confined to a published description of a single process, which might better have been omitted or supplemented. The remainder of the book summarizes the most important points of published descriptions of deposits throughout the world. Those interested in oil shales should have no hesitation in adding it to their libraries.

C. L. JONES.

THE PROGRESS OF ALLIED CHEMISTRY (Annual Report). Issued by the *Society of Chemical Industry*. Vol. 6, 1921. 7s. 6d. to members; 12s. 6d. to non-members, postpaid. Address 46 Finburg Sq., London, E. C. 2.

It is a pleasure to review this admirable and authoritative report on the progress of applied chemistry. It occupies much the same enviable position in industry which the reports of the Chemical Society do in theoretical chemistry. The report is subdivided into a very great many chapters, each chapter having to do with a particular field of chemical industry. Each chapter is compiled by an able critic in the special field and as a rule takes the form of a general review of the industry during the past year, followed by specific details as to progress made, with the names of the men who have made the contributions and the place where the article is published. The criticisms of such progress vary, of course, with the personality of the reviewer. This largely and quite rightly takes the form of a colorless announcement of the contribution. It usually is entirely too soon to pass a final and an adequate judgment on the value of a specific contribution. Occasionally, however, a few adjectives occur in the text which serve as an index of the reviewer's estimate of that particular work. While we must indorse the conservative practice which does not form a premature estimate, yet we do feel that the judgment of a man able to summarize the work done in the particular field is of inestimable value. We would, therefore, urge the reviewers not to lean too far backward in failing to give an estimate of the value of the work done. A reviewer selected by the Society of Chemical Industry may feel considerable confidence that his opinions will be received with respect throughout the industry. This will tend to make him conservative, naturally, but we sincerely hope it will not dull or sheathe the edge of his critical judgment, which is of most value to the readers of such a report.

We have been interested in the inclusion of a section entitled "Bleaching, Dyeing, Printing and Finishing." A chemical industry, to be sure, and one which has received from chemists and chemical engineers in this country all too little consideration. Any system of classification is difficult, and the custom in this country to regard fine chemicals as a much larger and inclusive class than do these reports is a source of some confusion. It would seem more logical to us to include, under a consideration of all organic chemicals, Coloring Materials and Dyes. The development of some organic materials has, I think, been overlooked or, if not overlooked, so placed as not to be easily accessible. For example, hydroquinone and metol have not been located.

With this criticism for omission or misplacement and the expression of the hope that the eminent reviewers will express their opinions of recent advances more freely, we may give vent to a distinct enthusiasm for the whole work and a praise which we hope will not become fulsome.

In general, most of the industries suffered from the widespread depression and the analysis of conditions in the individual industries is in almost every case keen and suggestive. In only one or two cases is there no attempt to make a general analysis of the status of each industry.

In many lines the statement is made that the depression which has existed throughout the industry has militated against research, due to the fact that the personnel has been largely dismissed. (This is also true in this country.) In very few lines is it said that notable advances have been made during the past year. Notable advances mean research, and research means a willingness on the part of manufacturing concerns to invest money in research and men. During the past year this has been practically eliminated. Again, referring to the review of coloring matters and dyes, the fearless statement of the reviewer in regard to the misuse of government subsidy in the dye industry of Great Britain is indicative of the best kind of review work. His criticisms are sound and constructive. It is a great pleasure to compliment the Society of Chemical Industry on continuing this very real contribution to applied chemistry. Technical men would do well to study this book and if only we could bring it to the attention of bankers and inventors who control too many of our chemical industries, we would feel that our mission in life had not been wasted.

CHARLES WADSWORTH, 3D.

ENTROPY AS A TANGIBLE CONCEPTION. By *S. G. Wheeler*, Eng. Lieut.-Commander, R. N. 76 pp., illus. New York: D. Van Nostrand Co., 1922. Price $3.

Many engineers and students of engineering are men of a wholly practical turn of mind, men who are by instinct doers, managers. The prime object of their studies is to acquire the tools which enable them to obtain results, to learn what to do; and not necessarily to learn why it is done.

Most of the methods employed in modern engineering find a basis in abstract mathematics. This is particularly true of thermodynamics, which is a science based on the hypothesis of an imaginary, ideal mathematical cycle which cannot be approached in practice. Such a theoretical basis for a science makes no pronounced appeal to the typical engineer. Consequently the whole subject of thermodynamics is more often than not only half digested by the man who must use it. He understands the way in which any set problem must be solved; but he distrusts the mathematics which must be employed, because he has not a sufficient grasp of the underlying principles to use these mathematics in a free and unhampered way.

Commander Wheeler has written a little book which is well called "an elementary treatise on the physical aspects of heat, entropy and thermal inertia." By a readily comprehensible analogy between the mathematically simple theory of kinetic energy and the obscure theories of thermodynamics, the reader is led by easy stages to a grasp of the physical conception of entropy and of the basis on which a steam chart is drawn.

This book cannot fail to be of value to all those—engineers and others—who are under the necessity of dealing with problems of steam engineering and who have not had the training in mathematics and abstract science necessary to a complete understanding of these problems. It is to be hoped the author will at some time extend his work to include more definitions; and the numerous and valuable charts and diagrams might be presented in a more clean-cut way to advantage. But as the book stands it is a worthy addition to the working library; and the author in writing it has pointed the way to a service which could well be done in other lines where practical men must use mathematics which they do not understand and hence distrust.

G. L. MONTGOMERY.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

American Electrochemical Society Moves

Headquarters Established in New York After 20 Years in Bethlehem, Pa.

After having been established at Lehigh University, Bethlehem, Pa., for about 20 years, the American Electrochemical Society has moved its national headquarters to Columbia University, New York City. This action was taken in order to facilitate the work of the secretary, Colin G. Fink, who has recently been appointed lecturer in electrochemistry and who will have charge of that division of the department of chemical engineering at Columbia University. The former headquarters was established in Bethlehem due to the fact that the late Joseph W. Richards, for many years secretary of the Society, was situated there as professor of metallurgy at Lehigh University. The present move has been under consideration for some time and will greatly facilitate the transaction of the Society's business.

In accordance with the recent amendment to the Constitution of the Society, the annual dues are now $8 and by action of the Board the annual charge to members for bound volumes will be $5 per year, effective Jan. 1, 1923. The charge for transactions to non-members will be $6.50 per volume and to public and scientific libraries $4 per volume.

The directors recently authorized the organization of a division of organic electrochemistry and appointed A. W. Burwell temporary chairman with the power to appoint his organizing committee and draw up a constitution and bylaws, to be submitted to the Board for approval at the Montreal meeting.

American Ceramic Society Summer Excursion Plans

"A family excursion: Bring yours!" Such is the slogan that the American Ceramic Society has adopted for its summer excursion meeting which is scheduled for Aug. 13 to 19 and will include visits to Rochester, Montreal, Ottawa, Kingston, Toronto, Hamilton, Niagara Falls and Buffalo. The trip will be made by boat and will be strictly an "outing," affording opportunity for a taste of camp life and the exploration of the Thousand Islands. Among the ceramic points of interest which will be visited are feldspar mills, enamel, glass, tile, brick and porcelain works and the famous Canadian feldspar mines at Verona.

$400,000 for Helium Research

An appropriation of $400,000 for research work and for the production of helium will be available during the fiscal year beginning July 1. The effort of the Senate to reduce this amount to $300,000 was unsuccessful, as the conferees on the War Department Appropriation bill accepted the House figure.

Advisory Committee Lays Plans for Chemical Exposition

Only American Exhibits to Be Admitted. Several Societies to Meet at Exposition

At a dinner meeting held at the Chemists' Club, New York on June 29, the advisory committee of the National Exposition of Chemical Industries considered ways and means to insure the continued success of the exposition at the eighth exhibit to be held in Grand Central Palace during the week of Sept. 11, 1922. One of the most important matters discussed was the type of exhibit that should be permitted. As in previous years, the management has been confronted with the problem of keeping the exposition free from objectionable exhibits and confining it to a strictly national exposition of chemical industries. After considerable discussion and the consideration of a number of special cases, the advisory committee officially decided that only American companies and American products should be admitted to the Exposition except on special approval of the committee. This general principle was adopted for the guidance of the management which will subsequently bring before the committee any cases that are not satisfactorily covered by the resolution.

The programs that are being arranged comprise special meetings of the American Ceramic Society, the Technical Association of the Pulp and Paper Industry and the newly organized Technical Photographic and Microscopical Society. In addition to these the committee planned to obtain addresses by popular leaders who have a full appreciation of the importance of developing our chemical industries and who will bring a message that will impress this fact upon the general public.

The management reported to the advisory committee the results of a meeting held with the recently organized Chemical Equipment Association at which a number of moot points were settled to the satisfaction of the exhibitors. At a subsequent interview between the management and the chairman of a special exposition committee appointed by the Chemical Equipment Association some further matters of interest to exhibitors were discussed, and it is felt that as a result of these conferences the atmosphere has been thoroughly cleared and all questions relating to policy of the management have been satisfactorily answered.

Those in attendance at the meeting of the advisory committee were: CHARLES H. HERTY, chairman, president of the Synthetic Organic Chemical Manufacturers Association; M. C. WHITAKER, vice-president and general manager of the U. S. Industrial Alcohol Co.; P. C. KINGSBURY, the General Ceramics Co.; L. H. BAEKELAND, president, the Bakelite Corporation; T. B. WAGNER, consulting chemical engineer; R. P. PERRY, the Barrett Co.; BERNHARD C. HESSE, General Chemical Co.; JOHN E. TEEPLE, president of the Chemists' Club; DAVID WESSON, past-president of the American Institute of Chemical Engineers; HENRY B. FABER, National Aniline and Chemical Co.; CHARLES F. ROTH and F. W. PAYNE, co-managers of the Chemical Exposition and H. C. PARMELEE, Editor of *Chem. & Met.*

Steel Alloy Plant for Canada

The Dominion Alloy Steel Corporation, Ltd., has been organized with an authorized capitalization of $7,500,000 8 per cent cumulative preferred stock, $7,500,000 of common stock and $2,500,000 of bonds, of which $5,000,000 of preferred and $4,400,000 of common stock have been issued. The company has purchased a site on the River Ste. Claire, at Sarnit, Ont., and will erect a plant, consisting of open-hearth and electric furnaces, rolling mills, machine shops and laboratories, for the manufacture of special alloys and high-carbon steels. The plant will be a duplicate of the United Alloy Steel Corporation's plant at Canton, Ohio, some of the directors and stockholders being interested in both concerns, and will have a capacity of 100,000 tons of steel yearly. The production of the plant will be made mainly with a view to supplying the automobile manufacturers of Canada.

Harry Ross Jones, director and formerly president of United Alloy Steel Corporation, is chairman of the board of directors; William E. Boyd, Toronto, president; George Simpson, formerly sales manager of the Steel Company of Canada, vice-president; and Bert H. McCreath, second vice-president.

Government Appropriation for Muscle Shoals Carries Provision for Delay of Work

Appropriation for Construction of Wilson Dam Passed by Both Houses but Will Not Become Available Until October 1 on Account of Pending Action on Ford Offer

BY A VOTE of 145 to 105 the House of Representatives, on June 24, agreed to concur in the Senate amendment to the War Department appropriation bill which appropriates $7,500,000 for the reopening of construction work on the Wilson Dam at Muscle Shoals. The vote carried with it, however, approval of an amendment by Representative James, of Michigan, which provides that no portion of the $7,500,000 is to become available before October 1. The purpose of the amendment was to give additional time for Congress to pass definitely on the Ford offer. The amendment was actively supported by those favoring the Ford offer who saw in the Senate amendment an effort to delay definitely any action on the Ford proposition. The House voted down, however, another amendment proposing a delay until January 1 before use could be made of the appropriation provided by the Senate amendment.

While the Senate was practically unanimous in its disapproval of the action of the House in delaying the time at which the $7,500,000 appropriation for the reopening of construction work on the Wilson dam at Muscle Shoals, nevertheless the Senate voted to concur in the House amendment. Senator Norris, the chairman of the Committee on Agriculture, which has jurisdiction over the Muscle Shoals proposition in the Senate, submitted a motion to disagree with the House amendment and urged that the bill be sent back to conference and so altered that the appropriation would become available immediately, as had been provided by the Senate. This motion was lost, however, by a vote of 28 to 32.

Delay Caused by Ford Offer

Friends of the Ford offer in the House not only declared that the Senate amendment was conceived with the idea of killing the Ford offer, but stigmatized it as a piece of hypocrisy—the drawing of a herring across the trail, in an effort to deceive the people.

Senator Underwood and other advocates of the Ford offer, declared that they are entirely at a loss to understand the logic which prompted the House to accept, by a majority of 40 votes, the amendment by Representative James, of Michigan, which postpones until October 1 the availability of the $7,500,000 appropriation.

Senator Norris pointed out that the amendment originated in an entirely regular way in the Committee on Agriculture and had the unanimous support of each member of that committee. It was brought on the floor, explained to and adopted by the Senate without any attempt at concealment or any resort to sharp practice. He declared that he is at a loss to understand why his committee and the Senate is accused of hypocrisy in the matter. Senator Underwood, who is admitted to be the most powerful friend of the Ford offer, concurred with that expression by Senator Norris and declared the amendment could not be construed as being anti-Ford.

Delay Will Seriously Handicap Construction Work

Senator Norris, in his remarks, pointed out that a delay of three months in making the money available means the loss of a year's time on a portion of the work. He referred to foundation construction, which can be conducted only during July, August and September, when the stage of the river is low. Senator Norris estimated that fully $2,000,000 less work will be done with the appropriation by beginning the work October 1 than would have been the case had it started July 1.

Senator Underwood explained that he would vote to concur in the House amendment because he feared that the appropriation might be lost altogether were the bill sent back to conference. "The gentleman," he said, "who expressed the opinion as to the hypocrisy of the Senate, evidently thought it would be hypocrisy to build this dam in July but not hypocrisy to propose to build it in October."

Some days before the vote on the conference report, Senator Norris had pledged himself to do all in his power to bring the Ford offer to a final vote at the earliest possible moment. He took the ground, however, after the action of the House, that he now is released from that promise. As chairman of the committee having jurisdiction in the matter he is in a position to delay the consideration of the Ford offer in the Senate.

Senator Lodge made the following contribution to the discussion: "The amendment of the House is economically wrong. It is not right or fair to the tax-payers. It ought not to be accepted by the Senate. The amendment by the House is indefensible."

Muscle Shoals as a Political Issue

From a political standpoint, the House amendment is regarded as a victory by the Democrats. While they admit that the Senate may not vote on the Ford offer before October 1, this delay does embarrass the Republican leaders in the House since they must either put the Ford proposition to a vote or be accused of an attempt to kill the Ford offer by refusing to allow it to come to a vote. Each party recognizes the political possibilities of the situation. Largely through the very active efforts of the Farm Bureau Federation, large support for the Ford offer has been developed among the farmers of the Middle-west and Northwest, sections where fertilizer is beginning to play an important part in agriculture. In addition Mr. Ford has a large personal following, which the Republican leaders do not want to antagonize, especially just before an election. As a result of this latest maneuver Muscle Shoals is expected to remain on the tapis for several months.

Safety Code for Conveyors and Conveying Machinery

American Engineering Standards Committee Announces Preparation of Safety Specifications

An important step toward the solution of an accident problem has just been accomplished through the decision of the American Engineering Standards Committee that the development of a safety code for conveyors and conveying machinery be undertaken.

The introduction of mechanical conveyors in many industries has eliminated a large proportion of the accidents resulting from the manual handling of materials. At the same time, it has introduced new hazards, many of which can be prevented by a more general agreement among both users and manufacturers of conveying equipment as to safe practice in the manufacture, installation and operation of such equipment.

The American Society of Mechanical Engineers and the National Bureau of Casualty and Surety Underwriters have been appointed joint sponsors for this code. All interested national organizations will be asked to co-operate in the formulation of the code. This code will be intended as a guide for the safe operation and maintenance of conveyors and conveying machinery coming under the following main divisions: gravity, belt, chain, flight-bucket, apron, screw and jigging conveyors, car hauls, aerial cableways, overhead trolley, and pneumatic tubes.

All shafting, pulleys, belts, link belts, chains, gears, sprockets, couplings, clutches, etc., used on and in connection with conveyors and conveying machinery will be covered in the mechanical power transmission code now in preparation.

Chemical Warfare Appropriation Will Go for Research

Plans for the allotment of the $600,000 appropriated for the use of the Chemical Warfare Service during the fiscal year beginning July 1 have not been perfected as yet due to the illness of Brigadier-General Amos A. Fries, the head of the service. It is known, however, that most of the money will be expended on research work and on defensive training of troops.

Society for Improvement of Engineering Education Attempts Move for Broader Training

At the annual convention of the Society for the Promotion of Engineering Education which was held recently at the University of Illinois, Charles F. Scott, of Yale University, outlined a new and broader vision of engineering education based on the needs and demands of industry. In tracing the parallel development of university education and the economic trend of industry in this country he pointed out that all basic industries are looking not only for trained technicians but leaders of production and in administration, leaders who have a through understanding of the relationship of engineering to the economic development of this country's resources and business requirements of the future. The building up of efficient teaching staffs, he declared, is one of the prime functions of the society for the promotion of engineering education if that organization is to lead the requirements of industry and develop men who are prepared to deal with the new and changing problems of engineering. The council of the society adopted the following resolutions for the broadening of its actions:

> Resolved, That the president of this society appoint a committee of 5 members, including himself, to study the development of the society for the promotion of engineering education and to formulate an answer to the question, "What can the society do in a comprehensive way to develop, broaden and enrich engineering education?" and further that this committee shall report, as early as feasible, formulations of the answer back to the council for action on the committee's recommendations.

At the last session of the Council of the S. P. E. E., the plan of the midwest deans for a five-year course was presented but not endorsed. The midwest deans agreed among themselves to go ahead as a separate unit and develop the plan as originally laid down at the meeting in Chicago on May 10.

New Section Established

The Council at the same meeting decided to establish a new section within the society composed of deans and directors of engineering schools. This is the culmination of a discussion on this subject which started at the New Haven meeting last year. The new section of deans of the society will deal with general administrative matters. This new section does not incorporate the organization of midwest deans which is a separate organization without connection with the Society, that is working out the five year course for engineers.

The keynote of the discussions was the development of teachers who can train engineers along the lines of the plans that are now being studied to to make university training more effective. The plan of instruction for freshmen now being followed at Purdue University as inaugurated and explained by Dean A. A. Potter created much discussion. This plan aims to stimulate the interest of the student early in his course by introducing engineering problems that appeal to his instincts and deal with actual situations calling for solutions designed to train him to think clearly, act quickly and calculate accurately. It is also a rough measure of his fitness to pursue engineering work. The instruction includes general lectures, inspection trips and simple engineering problems. The discussion brought out the fact that similar work is being conducted in several other colleges and much interest in the results of the plan after another year or so of its application was expressed.

Officers Elected

The following officers were elected for the coming year: President, Charles F. Scott; vice-presidents, D. S. Kimball, of Cornell University, and F. G. Higbie, of Iowa State University. New members appointed to the council are: M. W. Alexander, National Industrial Conference Board; Edward Bennett, Wisconsin University; H. S. Evans, University of Colorado; E. A. Hitchcock, Ohio State University; H. J. Hughes, Harvard University; C. E. Magnusson, University of Washington; G. C. Shaad, University of Kansas.

Safety Congress to Meet in Detroit

Prospects for Very Successful Meet—Program for Chemical Division

The program of the eleventh annual safety congress of the National Safety Council at Detroit Aug. 28 to Sept. 1 is now complete. Indications are that the 1922 convention will be the largest and most complete in the history of the National Safety Council. Public officials, industrial executives, well known authorities in research, science and education have volunteered to appear on the programs to do their bit for national safety.

Complete discussion of the various phases of industrial and public safety will be had at the meetings of the twenty different sections into which the Council's activities are divided. These meetings will cover safety problems in the automotive, cement, chemical, construction, metals, paper and pulp, packers and tanners, rubber, textile, woodworking, electric railway, public utilities, steam railroads, mining, public safety, educational, engineering, drop forge, health service and women in industry divisions.

All meetings will be held in the new Cass Technical High School which has just been completed as one of the finest educational institutions of its kind in the country. The main auditorium will accomodate more than 3,000 persons. Other commodious facilities for sectional and committee meetings are included in the same building. Practically all available space is taken for the safety exhibit which will be held in a large hall immediately adjoining the main auditorium. The dust explosion exhibit of the U. S. Department of Agriculture has been secured as a feature. Special outside exhibits including a Ford Motor Company exhibit, a model safety street car exhibit and a night parade to demonstrate safety headlights for automobiles are planned.

Program of Chemical Section

The chemical section is under the chairmanship of S. H. Kershaw, of the Hercules Powder Co. and E. J. Reiderer, of the Atlas Powder Co. G. E. Minshull of the E. I. du Pont de Nemours and Co. is secretary.

The first session will be held Aug. 29 at 9:30 a.m. After the business meeting, committee reports, etc., Walter G. Whitman, professor of chemical engineering at Massachusetts Institute of Technology will give an address on "Safe Handling of Materials in Chemical Plants." F. J. Hoxie, engineer and special inspector for the Associated Factory Mutual Fire Insurance Companies.

The second session of this division on Aug. 30 will be featured by the report of the industrial poisons committee of which A. L. Watson, of the Hooker Electrochemical Co., is chairman. A paper on "Benzol Poisoning, Its Occurences and Prevention," will be presented by Charles F. Horan, of the Hood Rubber Co.

Journal of Scientific Instruments

The British Institute of Physics, 10 Essex St., London, has issued a specimen number of a proposed monthly *Journal of Scientific Instruments*, to be devoted to methods of measurement and the construction and use of instruments.

Heavy Chemical Freight Rates Protested

In a complaint to the Interstate Commerce Commission, the Mathieson Alkali Works of New York alleges unreasonable rates on chlorine gas from Niagara Falls to points on the Baltimore and Ohio railroad, because of the failure of the railroad to allow mileage on the tank cars of the alkali company either for the outbound or the return movement. The commission is asked to establish reasonable rates and regulations governing the use of the alkali company's tank cars in liquefied chlorine gas traffic.

In the complaint of the Hercules Powder Co., an Interstate Commerce Commission examiner recommends that the rates on sulphuric acid from Danville, Ill., to Ishpeming, Mich., are unreasonable.

Alien Property Disposal Would Be Investigated Under Bill Now Before House

Chemical Foundation Included in Scope of Bill Calling for Explanation of Activities of Former Alien Property Custodian

A BILL embodying the principles recently announced by the President with regard to the disposition of alien property has been introduced in the House of Representatives. An understanding as to the matters covered by this legislation was reached at a recent conference between the President, the Secretary of State, the Attorney General and the Alien Property Custodian.

In urging the adoption of the bill in the House, Representative Woodruff, of Michigan, declared that the Chemical Foundation and Bosch Magneto cases are instances of flagrant maladministration of trust property, calling for swift and drastic action. He referred to George J. Corbett as chief aid of former Custodian Garvan in putting over the "Chemical Foundation deal," the former becoming secretary of the concern on its organization and receiving substantial compensation out of trust properties for services rendered the custodian. He also said the matter of L. Vogelstein Co. in relation to the metal situation should be investigated.

Miller Interprets Scope of Bill

Discussing the proposed bill, Colonel Thomas W. Miller, the Alien Property Custodian, said: "One section provides for the return to the former owners of all property out of every trust not exceeding in value in any case the sum of $10,000. This means that smaller property owners whose property is valued at $10,000 and under will receive their property back in full at this time. Of the thirty-two thousand active trusts now administered by the Alien Property Custodian about 93 per cent are of the value of $10,000 and under. In addition, the property in every trust in excess of $10,000 will receive that sum from the Custodian on account.

"Another section provides for the extension of time in the filing of suits allowed under the various sections in the 'Trading with the Enemy Act,' made necessary by the expiration of said period under the present act.

"The third section refers to assignments and limits attorneys' fees.

"Section four provides means by which the President may, at his discretion, transfer funds on deposit in the Treasury so that the Alien Property Custodian may deposit the same in banks, said deposits being insured by Liberty Bonds as collateral, with a view to utilization in the economic relations between this country and Europe pending the time such funds are held for final disposition by this government.

"The last section will clear up claims of naturalized American citizens who have been under a presumption of expatriation by reason of their absence from the United States before the war and whose property was seized as a result of their being in Germany or an enemy country during the state of war.

"This bill embodies the recommendations made by the Alien Property Custodian's office to President Harding and represents the initial step of this administration in the final disposition of of the alien property situation. A claims tribunal will undoubtedly be created by the treaty under negotiation between the Department of State and the German Government which will adjudicate and settle the question of American claims against Germany and their relation to the alien property still to be held."

Chemical Foundation Suits Explained by Choate

In regard to widely published statements concerning certain law suits which have been instituted by the Chemical Foundation against several manufacturers, Joseph H. Choate, Jr., counsel for the Chemical Foundation has authorized the following statement:

> Statements which have recently appeared in the press in regard to the commencement of certain suits by the Chemical Foundation against a number of manufacturers have apparently produced a false impression. Some of these intimated that the companies thus sued were charged with improper, if not unlawful, acts. Nothing could be further from the truth. The suits are entirely friendly actions, brought to establish the title of the Foundation to the funds long since paid by the defendants as royalties for the use of patents now owned by the Foundation, under licenses issued by the Federal Trade Commission. The trading with the enemy act provided that these funds be held in the U. S. Treasury as a trust fund for the owner of the patents and for the licensees, as their respective rights might be determined by suits to be brought by the owner against the licensees. This provision compelled the Foundation, which would have no difficulty in agreeing with almost all of the licensees, to bring such suits as the only means of securing from the Treasury moneys to which it is entitled. The companies sued have, generally speaking, done everything that they should in the matter and nothing that they should not.

Marconi to Receive Medal

The John Fritz medal will be presented to Senator Guglielmo Marconi in the auditorium of the Engineering Societies' Building, 29 West 39th Street, New York, Thursday evening, July 6.

Federal Phosphorus Co. Denies Removal Report

Theodore Swann, president of the Federal Phosphorus Co., Birmingham, Ala., has issued a statement denying recently published reports to the effect that his company contemplated the removal of its Anniston plant to Jacksonville, Fla. The conference between the City Commission of Jacksonville and T. L. Long, who was reported to be the representative of the Federal Phosphorus Co., was entirely unauthorized and without the knowledge of Mr. Swann. There is no intention of moving the plant.

Metallographic Institute Organized in Sweden

Result of Co-operation of Government, Educators and Manufacturers

A Metallographic Institute was formally inaugurated in Stockholm, Sweden, on June 1. The exercises were presided over by Professor Svante Arrhenius and were attended by representatives of Stockholm University, the Ironmasters' Corporation (Jernkontoret), the Engineering Academy and the national government. Preliminary steps in the organization were instituted by Stockholm University and the new Institute has been financed by contributions from the leading manufacturers of Sweden, in co-operation with Jernkontoret. The Government has placed suitable quarters at the disposal of the Institute.

Carl Benedicks, the well known physicist and authority on physical metallurgy has been appointed head of the Institute. The object as embodied in the declaration of its founders is "To practice and further scientific resarch in metallography and allied subjects." In his inaugural speech, Dr. Benedicks announced that one of the actual aims of the Institute, and one upon which they have already embarked, is research work designed to determine the space lattices of atoms in pure metals and alloys. Besides such purely scientific research work, the Institute will answer questions, furnish advice and report upon specific metallographic problems of a more practical nature.

The Institute is thoroughly equipped with instruments and appliances of the most modern type. It has a special room containing several electric melting furnaces, including a Northrup high-frequency furnace, considerably improved by new appliances added by the staff of the Institute. It is also very well equiped with measuring and recording apparatus, including a double string galvanometer and a powerful du Bois electromagnet. The laboratories for microscopic photography and chemistry are very well equipped. In addition to this, the Institute has its own machine shop, possessing sufficient precise tools for the manufacture of new instruments and appliances which will be required from time to time as the work proceeds.

Chemical Warfare Gas Used as Fumigant

Cyanogen Chloride May Supplant Hydrocyanic Acid as Result of C. W. S. Research

Cyanogen chloride is expected to supplant hydrocyanide acid gas for ship fumigation as a result of co-operative research and experimentation on the part of the Chemical Warfare Service and the Public Health Service. In the course of this work it was developed a few months ago that the greatest objection to hydrocyanic acid gas could be overcome by mixing it with ordinary military tear gas. This ingredient made it possible to recognize the presence of the gas in the holds of vessels. As the work progressed, however, it was found that cyanogen chloride gas serves all the purposes accomplished by hydrocyanic acid gas and has the advantage of being readily recognizable.

This work along with the progress which has been made in the use of toxic materials in anti-fouling paints is pointed to at the Chemical Warfare Service as typical of what is being done by the Service in its co-operative research with other Government bureaus. The work on anti-fouling paints has been done in co-operation with the Navy's marine biological laboratory at Beaufort, S. C. Every effort is being made by the Chemical Warfare Service to make available to all concerned the results of the intensive work done by scores of chemists during the war on toxic materials.

Congress Will Not Incorporate Scientific Societies

The subject of incorporation of scientific societies was brought up in the House of Representatives by the introduction of a bill proposing the incorporation of the American Mathematical Society. Objections by Representatives Stafford of Wisconsin and Huddleston of Alabama prevented the passage of the bill. The former expressed the conviction that if Congress intended to incorporate every scientific society it should do so by a general law and not in special bills for each society and referred to the possibility that the American Automotive Society and the American Chemical Society might desire incorporation. Representative Huddleston opposed incorporation of societies by Congress on general principles.

Treasury Department Ruling on White Lead

The Treasury Department has ruled that the allowance for valueless waste incurred in the Carter process of manufacturing white lead shall not exceed 1 per cent of the quantity of lead used. The ruling was issued in connection with the payment of the drawback on white lead made from imported lead.

Civil Service Openings

The United States Civil Service Commission announces open competitive examinations for junior microanalyst in the Bureau of Chemistry at a salary of $1,400 to $1,800 and for junior aids in the Bureau of Standards at salaries of $540 to $840 per year. Junior assistants are afforded the opportunity of continuing their college work at local universities. Application should be made on form 1312.

Personal

F. W. BARKER, JR., who has been in the chemical division of the manufacturing department of the National Aniline and Chemical Co., Inc., has severed his connection with that company and is now associated with The Kaumagraph Co.

H. C. CUMMINS has been elected president of the Shaffer Oil and Refining Co., Chicago, Ill., to succeed GEORGE N. MOORE, resigned. Mr. Cummins was formerly vice-president and secretary, and has been succeeded as vice-president by W. H. CANNADY, heretofore manager of the refining department; and as secretary by W. R. FRANCISCO, who will also act as treasurer.

E. L. DOHENY has been elected chairman of the board of the Mexican Petroleum Co., of New York, N. Y., and its subsidiary organizations. HERBERT G. WYLIE, formerly vice-president and general manager, has been elected president to succeed Mr. Doheny.

C. R. DOWNS, formerly chief chemist of the research laboratory of The Barrett Co., Edgewood, N. J., is now with the National Aniline and Chemical Co., Buffalo, N. Y.

F. B. FOLEY has been relieved as a member of the drill steel field-survey committee and has returned to his station at the Bureau of Mines in Minneapolis, where he will resume his experimental work on this subject. C. Y. CLAYTON and H. S. BURNHOLZ are continuing this joint field study of the Bureau of Standards and Bureau of Mines, visiting the various mines which are co-operating in the drill steel study.

ERNEST A. HERSAM, of the University of California, has been appointed by the Bureau of Mines as a metallurgist to work on the survey of milling methods which is being done in co-operation with the American Institute of Mining and Metallurgical Engineers. Prof. Hersam's headquarters will be at the Massachusetts Institute of Technology where he will be associated with Prof. Locke. The work will include an extended survey under the general chairmanship of G. H. CLEVENGER of the Committee on Milling Methods of the Institute. This work also involves co-operation with the pulverizing committee of the Engineering Division of the National Research Council.

Senator GUGLIELMO MARCONI will receive the John Fritz medal July 6, 1922, in the auditorium of the Engineering Societies Building, New York.

I. E. NEIFERT, a chemist formerly with the Chemical Warfare Service, who now is a member of the faculty at Knox College, Galesburg, Ill., has been engaged by the Department of Agriculture to do research work during the Summer on grain fumigation. The Department is very anxious to develop a fumigating agent which does not carry with it a fire or poison hazard. Particular attention is to be given to the effects on grain of the use of chlorpicrin.

Dr. R. F. RUTTAN, the retiring president of the Society of Chemical Industry, and Dr. A. T. CHARION will represent Canada and the Canadian Institute of Chemistry at the Third annual meeting of the International Union of Pure and Applied Chemistry.

JAMES A. STADER has been appointed chief of the minerals section, Iron and Steel Division of the Bureau of Foreign and Domestic Commerce. He began work in the new position on July 1, giving special attention to the nonferrous metals and non-metallic mineral products, for which there has been no commodity division of the Bureau formerly. Mr. Stader is a graduate of the University of Missouri, and has had extensive experience in the Far East, Mexico and Europe. He was for some time a technical advisor of the Inter-Allied Industrial Commission dealing with problems of reparations of coal, oil and mineral products. He leaves a temporary connection with the Seiberling Rubber Co. to accept this Government appointment.

Prof. E. W. WASHBURN, head of the department of ceramic engineering, University of Illinois, will succeed Dr. FREDERICK G. COTTRELL as chairman of the division of chemistry and chemical technology of the National Research Council.

Obituary

ALEXANDER R. SMOLEY, and not Alexander R. Smalley, is the name that should have appeared in the obituary notice in our issue for June 21. His age was 27 and not 25 as given.

FRANK L. STILES, president of a number of New England brick manufacturing companies, died at his residence in North Haven, Conn., June 9, in his 69th year. At the time of his death he was president and treasurer of the I. L. Stiles & Son Brick Co., North Haven; and also president of the following companies: North Haven Brick Co., North Haven; Stiles & Reynolds Brick Co., Berlin, Conn.; Stiles and Hart Brick Co., Taunton, Stiles & Hart Brick Co., Taunton, Bridgewater, Mass. He enjoyed a national reputation in the industry, and was at one time a member of the Connecticut State Legislature.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

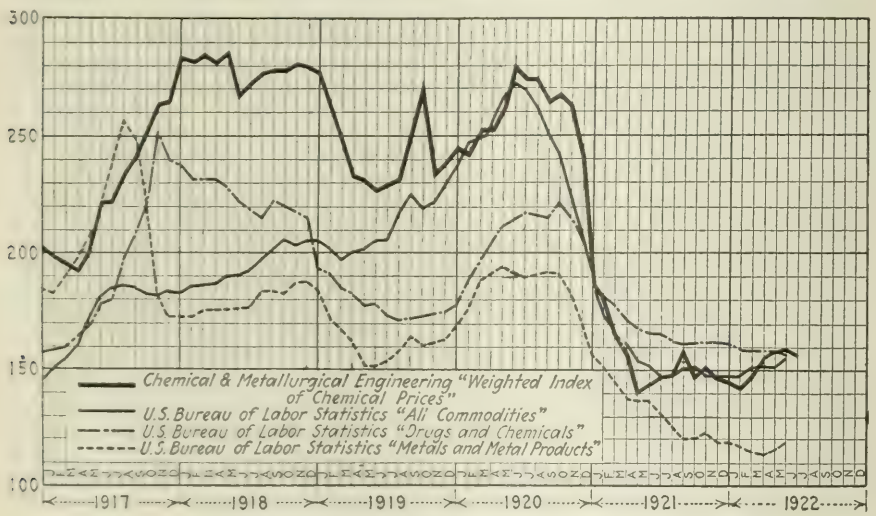
A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Business Conditions Steadily Improving

A Review of Fundamental Economic Conditions Shows That the Gains in the General Business Situation Are Becoming More Evident in the Chemical and Allied Industries

TO SURVEY the progress of business during the first six months of 1922 is to gain a new confidence in the thoroughness of its remarkable recovery. Each month since January has shown a gradual, consistent betterment in underlying business conditions and this has been accurately reflected in practically every line of industry. Improvement is still the predominating note in the business situation, notwithstanding that the gains made during June were somewhat less pronounced—due perhaps to the fact that certain industries have reacted to the common tendency for a seasonal lull in activities. For the most part, however, the basic lines of manufacture represented by the chemically controlled industries have continued to show the stimulating effects of business revival and the return of confidence in industry.

Factors favoring this improvement, or resulting directly from it, are the increased production in certain basic industries, the unusual building activity, the stable if not increasing prices, the growing commodity consumption as measured by car loadings, and the decrease in unemployment and in business failures. The trump cards in the hands of the business pessimist, on the other hand, are the continued labor difficulties in the coal fields and textile centers, the threatening railroad tie-up and the apparent reaction taking place in the stock market. Fortunately, there is growing evidence, however, that these cards may never be played. The administration's efforts toward reaching an early settlement of the coal strike and the widely held belief that the present decline in the market is only a temporary set-back are factors from which significant developments may yet be expected.



THE TREND OF WHOLESALE PRICES,
1917-1922

"CHEM. & MET." WEIGHTED INDEX OF CHEMICAL PRICES

Base: 100 for the Year July 1, 1913, to June 30, 1914

This week	157.52
Last week	156.89
July, 1921	145
July, 1920	274
April, 1918 (High)	286
April, 1921 (Low)	140

This week's index number shows a net gain of 63. Slightly lower prices for soda ash and caustic soda were more than compensated by advances in ammonium sulphate, barium chloride, copper sulphate, glycerine and linseed oil.

The Industrial Situation

Before considering any of these factors in greater detail, however, it is worth while to give attention to how the situation is being reflected in the different industries.

Iron and Steel. May, with a total production of pig iron amounting to 2,306,679 tons, represents a gain of 11.3 per cent over April and of 16 per cent over the first five months of 1921. Steel ingot production of 3,099,155 tons is 114 per cent of the output of May, 1921 and the largest since October, 1920. Furthermore, steel production in 1922 is 33⅓ per cent greater than during the corresponding period of last year.

Automobile. The National Automobile Chamber of Commerce estimates the May production of cars and trucks at 252,167, an increase of 15 per cent over April and 54 per cent above May, 1921. This is the largest previous month since March, 1920. At present only 14 per cent less people are employed in the Detroit industries than at the time of the 1920 peak.

Petroleum. While crude oil production has been continuing at a low rate, it is interesting to know that the output of gasoline in April, the latest month for which statistics are available, amounted to 472,920,000 gal. This is another new high record and compares with a consumption of 385,564,000 gal.

Construction. All previous construction records had been broken in April but apparently May's building contracts exceeded those of April by over 3 per cent. According to the F. W. Dodge Co., the May total for 27 northeastern states was $362,590,000 which was 50 per cent greater than in May of last year.

Leather. The leather industry as a whole is encouraged by the broader demand for its products. The recent price adjustments have done much to stimulate the tanning industry which has been suffering from the very narrow margin between hide costs and leather prices.

Paper. The total newsprint produced in May, 1922 was 129,950 net tons—an increase of 65 per cent over the 78,868 tons produced in May, 1921. The output during the first five months of 1922 totals 562,912 tons as compared with 528,678 tons during the corresponding period of last year.

Rubber. This industry has of course benefited by the activity in the automobile industry. Reports are to the effect that the Akron plants are running at maximum capacity based on present working forces. It is expected that production will continue at an even keel during July and any seasonal slackening will scarcely have effect before August.

Drugs and Chemicals. Valuable as an index of business sentiment are the results of a questionnaire on business revival sent to a trade group within this industry by the National Institute of Credit. The question: Has the revival of business activity reached your industry? was answered affirmatively by 86 per cent of the group.

Paint and varnish. One hundred per cent of the paint and varnish group testified to the effects of business revival, 78 per cent reported greater sales for May, 1922, than in May, 1921, and all but 4 per cent declared that May sales had exceeded those of April.

Cement. This industry is having difficulty in supplying the demand caused by the large volume of construction now under way. May figures, recently released by the Geological Survey, show an increase in production of 1,895,000 bbl. over that for May, 1921.

Wholesale Prices

Commodity prices since the first of the year have shown marked advances and it is only recently that the tendency to remain stationary has become evident. Bradstreet's monthly index during the past year has advanced ten times and decreased only twice and then to a minor extent. Wholesale prices according to this index are now 12.1 per cent above last year's.

The U. S. Bureau of Labor Statistics has recently revised its index numbers on the basis of a regrouping of commodities and the use of 1919 census data for weighting purposes. Unfortunately, this revision was not announced in time to make the necessary changes in the accompanying chart, which is continued on the old basis. The new index for all commodities is 143 for April and 148 in May, which is a most significant advance.

Chem. & Met.'s weighted index of chemical prices recorded a slightly lower level for June. This index had averaged 158.04 for April, 159.32 for May and declined to 157.48 for the month of June.

Other Significant Developments

Car loadings, which under certain circumstances may be considered a reliable index of distribution and therefore of consumption, have increased steadily. Loadings for the week ended June 17 amounted to 860,722 cars, the largest number of cars loaded in any one week since October 22, 1921. This compares with 750,645 in the week of June 3 and 846,002 in the week ended June 10. The largest increase was in merchandise, less than carlots of miscellaneous freight and ore loadings.

The financial situation has been featured by wide fluctuations in the markets for industrial stocks and foreign exchanges. The almost steady advance of the stock market which started last August experienced its first substantial set-back during June. However there is abundant evidence that this is a temporary reaction brought on by the wild speculation characterizing dealings in many issues. In the case of some of the chemical companies the reaction has caused almost disastrous depreciation. On the other hand certain oil stocks, notably those of Mexican Petroleum and allied companies, reached new levels during the speculative rise and have since maintained substantial gains.

Chemical Market During Second Quarter of 1912

THE COMMODITY MARKETS for chemical and allied products were without significant developments during the three months ended July 1, 1922. With the exception of a few of the more important basic materials, the improvement has been only moderate. Noticeable price fluctuations have for the most part been limited to items of a speculative nature. Minor changes have had a tendency to keep the market active, however, particularly to small-lot buyers.

Market Features

Among the important features of the market has been the significant recovery of barium products. Barium chloride had been quoted at $52 per ton in January, but steadily increased in price until it had reached a new high record of $105 in May. Competition, especially from increased imports, has tended to lower prices during June and at the end of the month dealers were quoting $95 per ton. The prussiates have also attracted a great deal of attention because of their wide fluctuations. Yellow prussiate of soda opened the year at 16c. per lb. During February and March it advanced to 18¼c. but declined in April to 16½c. per lb. The advance was renewed in May, however, and a new high level was established at 25c. per lb. June prices have averaged about 22c. Yellow prussiate of potash has shown a similar improvement, advancing from 25c. per lb. in January to 32c. toward the end of June. Red prussiate has been exceedingly scarce and prices as high as 90c. per lb. have been reported.

Caustic soda has been something of a disappointment to the producers, who claim that prices are not in line with the unusual heavy domestic and export demands. Prices, however, have shown considerable improvement. They opened the year at $3.25 per 100 lb. and steadily advanced to $3.70 in April and then to $3.90 per 100 lb. in May. June prices were reported around $3.80 per 100 lb. Manufacturers of oxalic acid increased prices from 11½c. per lb. in April to 14c. per lb. in June. Improved demand and higher costs have been directly responsible for the increase. Copper sulphate showed a net advance of ½c. per lb. during the interval.

Copperas, potassium bromide, acetate of soda, fluoride of soda, barium carbonate, salt cake and tartaric acid are other of the more important items to show increased prices during the second quarter. On the other hand, a number of declines were recorded. Perhaps the most important is in the case of sulphuric acid, the market for which is at present below pre-war levels. The decline since April has amounted to about $2 per ton and 66 deg. acid in tank cars, is now quoted at $15 per ton. Granular zinc chloride, nickel salts, formaldehyde, acetate of lead, acetic acid, methanol, glycerine, potassium bichromate and ammonium sulphate have also recorded fractional declines.

A monthly comparison of the average prices of 45 important chemicals in the New York market during the past six months is to be found in the accompanying table.

A SIX-MONTHS' REVIEW OF THE PRICES OF 45 IMPORTANT CHEMICALS, JANUARY-JULY, 1922

Article	Unit	Average Price for Month of— Jan.	Feb.	March	April	May	June	Price on July 1
Acetic acid, glacial	Lb.	$0.10	$0.09	$0.09	$0.09	$0.09	$0.08½	$0.08½
Muriatic acid, 20 deg.	100 lb.	1.25	1.15	1.15	1.10	1.10	1.10	1.10

The New York Market

NEW YORK, July 2, 1922.

Practically the only trading noticeable in the chemical market during the past week was for small lots of comparatively unimportant commodities. Oxalic acid has been an outstanding feature of the week's activities. Producers have announced an advance at the works and consumers have been buying in moderate proportions. Acetate of soda continued to display a very firm attitude and prices were quoted higher during the latter part of the week. Tartaric acid remained strong, with a good seasonable inquiry recorded from the consuming trades. Copper sulphate is somewhat higher on spot and supplies seem to be very scarce. Caustic soda has shown the effects of its prolonged activity and prices have declined to $3.75 per 100 lb. for export. Potash alum has also been reduced by leading dealers, in addition, prussiate of soda and barium chloride have recorded slight decreases.

GENERAL AND SPECIAL CHEMICALS

Acetate of Soda—It is rather doubtful if better than 6½c. per lb. can be done for spot goods. Large producers are quoting 5½@6c. per lb., f.o.b. works, depending on quantity.

Bicarbonate of Soda—Manufacturers quote $1.75 per 100 lb. for barrels, f.o.b. works. There has been no outstanding features of interest in this market, outside of regular contract shipments.

Caustic Soda—The demand for this product has slackened considerably and July shipment is being offered at $3.75 per 100 lb. f.a.s. The domestic demand continued rather steady with 3¾c. per lb. named for spot goods. Contract prices remain at 2½c. per lb. basis 60 per cent, f.o.b works, for car lots.

Copper Sulphate—The spot market is exceptionally strong with goods practically sold up and dealers quoting July material around 6½c. per lb.

Muriatic Acid—Large contracts for the 18 deg. acid have been placed as low as 1c. per lb. while the 20 deg. is held at $1.10 per 100 lb.

Oxalic Acid—Sales for spot goods have been recorded around 14½@15c. per lb. Material at the works is quoted at 14½@14¾c. per lb.

Potash Alum—Foreign stocks have depressed prices in the local market to 3c. per lb., with the range from 3@3½c. per lb.

Sulphuric Acid—Producers of this material quote the 66 deg. in tanks at $15@$17 per ton and drums at $18@$20 depending upon the quantity. Sales of 60 deg. were recorded at $9.50@$10 per ton.

WAXES

Beeswax—Crude wax was somewhat easier during the week, due to the increased stocks. Pure white wax was held at 40@45c. per lb.

Candelilla Wax—Spot material was exceptionally scarce and prices ranged around 40c. per lb. for odd lots.

Carnauba Wax — Material on spot was offered in larger amounts than have been noted for several weeks and prices were easier. No. 3 North Country was available at 16½c. per lb. No. 1 regular was quoted at 40c.

Japan Wax—A better inquiry was noted for this material and prices remained steady during the interval. The market for spot goods was held around 16@16½c. per lb. Forward business was transacted at 15c. per lb.

NAVAL STORES

Turpentine—During the early part of the week prices showed an advance from $1.25 per gal. to $1.48. Consumers and exporters were not eager to purchase at these high levels and prices reacted to $1.25 per gal. Quotations heard during the latter part of the week ranged around $1.30 per gal.

Rosins—The market showed the effects of the sudden decline in turpentine and all grades were reduced from 5 to 20c. per bbl. B-D was quoted at $5.40 per bbl. and W-G, W-W at $7.65@$8.30 per bbl.

The Iron and Steel Market

PITTSBURGH, June 30, 1922.

The steel market has grown progressively quieter in the past six or eight weeks, as to the actual tonnage turnover, and now at the beginning of the July-August midsummer period is ready for the dullness that usually characterizes those two months.

The trade is prepared for a dull period in the market. The mills are well sold up and buyers as a rule are well covered. In many departments mills are sold up very fully for two months and in some cases for a longer time. Merchant steel bars, in particular, are well sold ahead for about three months.

There is good ground, therefore, for expecting the steel market to weaken in case there is little activity for a number of weeks, or perhaps even for two months. The mills are really quite well fortified. They have more business on their books than even the more sanguine expected at the beginning of the year.

MILLS CONSERVATIVE

The mills as a rule refuse to admit that the lighter turnover in steel products in the open market is due to a change of attitude on the part of buyers. The mills state that the cause is their own reserve in the matter of selling, that they could book large additional tonnages if they cared to accept the business. The mills have endeavored as far as possible to limit their commitments to tonnages sufficient to cover the known requirements of customers.

While it is no doubt true that mills are conservative and could secure more business, in contracts or other form, than they are accepting, it does not follow that buyers also have not become somewhat more conservative. There is probably less disposition than two or three months ago to buy all the steel the mills will sell. There have been developments that would cause buyers to recede from their former position. There is, probably, no decrease in the rate of consumption and no diminution in the good prospects of steel consumers, but there are two developments of consequence, one being the maintenance of steel production in face of the coal strike, the other being the disinclination of steel prices to advance much if any beyond their present level.

Steel sellers and steel buyers alike have ground for allowing the market to drift for a time, and as to the future the chief point to be observed is which party shall first come into the market again in a large way. The crucial test will probably come shortly before or after September 1. The preponderating view seems to be that the mills will have the advantage at that time, whereby there may be a strong market for some time. On the other hand, it is doubtful whether such production of steel as has obtained lately can be continued beyond the end of the present year.

STEEL PRICES

Finished steel prices are quotable as follows: Bars, shapes and plates, 1.60c to 1.70c.; hoops and bands, 2.40c. to 2.50c.; blue annealed sheets, 2.40c. to 2.50c.; black sheets, 3.15c. to 3.30c.; galvanized sheets, 4.15c. to 4.30c.; automobile sheets, 4.50c. to 4.75c.; tin plate, $4.75; wire nails, $2.40 to $2.50; standard steel pipe, 71 per cent basing discount. In commodities in which a price range exists the higher price is usually for early delivery, though the character of specifications has something to do with the price.

THE COAL STRIKE

Rumors are prevalent as to operators beginning to make an effort to break the coal strike next week, these referring both to the Pittsburgh district operators, whose mines have been union, and to the Connellsville region, which has been nonunion for over 30 days, but which has had strikes that hang on rather well. Production in the Connellsville region has been increasing for almost two months, but at a very slow rate, close comparisons being necessary to show any change.

Connellsville coal weakened about 10 cents a ton late last week, but this week has regained the loss, being now quotable at $3.50 to $3.75 for steam mine-run. Connellsville coke is about 50 cents higher in the week, at $8.00 to $8.50. An interesting point is that there is practically no market in regular foundry coke. At most operations it is found difficult to produce coke of regular foundry grade, *i.e*, carefully selected, and rather than jeopardize reputations several operators are offering their coke as coke.

The pig iron market remains practically stagnant, with quotations unchanged, though now largely nominal, at $25 for Bessemer and basic and $24 to $25 for foundry, f.o.b. valley furnaces.

The Chicago Market

CHICAGO, Ill., June 27, 1922.

The demand for industrial chemicals during the past two weeks was rather dull but a slightly better movement was in evidence today. Consumers are holding off to a certain extent waiting for the lower freight rates which will be effective after July 1. This, and the approach of the slow summer season are the reasons given in most quarters for the present dullness and it is also believed that the uncertain tariff situation is having an adverse effect on the market. Prices have been very steady and only a few adjustments were noted while stocks in the hands of both jobbers and consumers were reported as low.

GENERAL CHEMICALS

The alkali market was without change and the movement was only routine. *Ground caustic soda* 76 per cent was quoted at $4.35@$4.50 per cwt. for moderate lots and the solid at $3.85@$3.95. *Caustic potash* lacked quotable change and was reported to be moving in a fair way at 6½@6¾c. per lb. for the 88-92 per cent material. *Soda ash* was quiet with only a routine movement reported. The 58 per cent material was quoted in cooperage by manufacturers or their agents at $2.20 @$2.30 per cwt.

Alums were in a firm position with prices generally maintained. *Ammonia alum* was quoted at 3¾@4¼c. per lb. for the lumps and 4¼@4¾c. for the powdered. *Potash alum* was in fair demand with the lumps available at 4½@5c. per lb. and the powdered at 5½@6c.. *Barium* products were in an easier position with imported material for shipment from the East available at lower prices. *Barium chloride* was offered at $100 per ton for moderate quantities. *Copper sulphate* was very firm and scarce with practically all holders asking 6½@7c. per lb. for the small lots that they had. Only a routine demand was reported for *sal ammoniac* and the prices were unchanged at 7¾@8c. per lb. for the white granular and 17@18c. for the lump. *White arsenic* attracted but little attention and was available at 8c. per lb. *Carbon bisulphide* was rather slow and only small lots changed hands at 7@ 7½c. per lb. *Carbon tetrachloride* was unchanged both as to demand and price. Large drums were available at 10c. per lb. *Formaldehyde* was very dull and weak with at least one factor offering single bbl. lots at 9c. per lb. delivered.

Refiners advanced their schedules on C. P. *glycerine* to 14¾c. per lb. bulk basis but the demand continued light.

The bichromates were without change in price and moved only in a routine way. *Sodium bichromate* of standard brand was available at 9c. per lb. in single cask lots and similar quantities of the potash salt at 11¾c. One holder was asking $1 per lb. today for *red prussiate of potash* for spot delivery. Small lots were available for shipment from the East at 85@90c. but no quantities were available at any price. The *yellow prussiate of potash* is in a very firm position and only small supplies were available at 34@36c. per lb. *Potassium permanganate* was slightly firmer at 16@16½c. per lb. for the U. S. P. small crystals.

LINSEED OIL

A prominent factor in this field reports a good movement of the oil and says that the tendency is toward slightly higher prices. The movement which is described as good consists mainly of small lots as there is a reluctance on the part of the consumer to anticipate his requirements very far ahead. The boiled oil was quoted today in 5-drum lots at 93c. per gal. and the raw in similar quantities at 91c.

Turpentine is apparently too high priced at the present time to move in very large quantities although dealers report a very good volume of business for small or moderate lots. Today's price for 5-drum lots was $1.25 per gal. *Rosin* was not moving as well as turpentine and the WG grade was quoted at $9 per 280 lb. for less than car lots.

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.14 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.50 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.23 — .26
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb	.32 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — .95
Meta-phenylenediamine	lb.	.95 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.10 — 1.20
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06 — .07
Naphthalene, balls	lb.	.07½ — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.11 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17
N-W acid	lb	1.15 — 1.30
Ortho-amidophenol	lb.	2.40 — 2.50
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75
Ortho-nitro-toluene	lb.	$0.10 — $0.13
Ortho-toluidine	lb.	.14 — .18
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.17 — .20
Paranitroaniline	lb.	.72 — .75
Para-nitrotoluene	lb.	.55 — .65
Para-phenylenediamine	lb.	1.55 — 1.60
Para-toluidine	lb.	.90 — 1.00
Phthalic anhydride	lb.	.35 — .38
Phenol, U. S. P., drums	lb.	.14 — 15
Pyridine	gal.	1.75 — 2.75
Resorcinol, technical	lb.	1.30 — 1.35
Resorcinol, pure	lb.	1.75 — 1.80
R-salt	lb.	.60 — .70
Salicylic acid, tech., in bbls.	lb.	.25 — .25½
Salicylic acid, U. S. P.	lb.	.26 — .26½
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.27 — .32
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.14 — .18
Sulphanilic acid, crude	lb.	.24 — .26
Tolidine	lb.	1.20 — 1.30
Toluidine, mixed	lb.	.30 — .35
Toluene, in tank cars	gal.	.25 — .28
Toluene, in drums	gal.	.30 — .35
Xylidines, drums, 100 gal.	lb.	.40 — .45
Xylene, pure, in drums	gal.	.40 — .45
Xylene, pure, in tank cars	gal.	.45 — ....
Xylene, commercial, in drums, 100 gal	gal.	.33 — .35
Xylene, commercial, in tank cars	gal.	.30 — ....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Bayberry Wax	lb.	$0.21 — $0.22
Beeswax, refined, dark	lb.	.30 — .32
Beeswax, refined, light	lb.	.34 — .35
Beeswax, white pure	lb.	.40 — .42
Candelilla, wax	lb.	.40 — .42
Carnauba, No. 1	lb.	.40 — .42
Carnauba No. 2, North Country	lb.	.24 — .25
Carnauba, No. 3, North Country	lb.	.16½ — .16¾
Japan	lb.	.16 — .16½
Montan, crude	lb.	.04½ — .04¾
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04½ — ....
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02¼ — ....
Paraffine waxes, refined, 118-120 m.p.	lb.	.03⅞ — .03¼
Paraffine waxes, refined, 125 m.p.	lb.	.03½ — .03¾
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 — .04¼
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½ — .04¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.05 — .05¼
Stearic acid, single pressed	lb.	.09 — .09½
Stearic acid, double pressed	lb.	.09½ — .09¾
Stearic acid, triple pressed	lb.	.10½ — .10¾

Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.25
Pinewood creosote, ref.	gal.		.52

Fertilizers

Ammonium sulphate, f.a.s., N.Y.	100 lb.	3.35 —	3.45
Blood, dried, f.o.b., N. Y.	unit	3.50 —	3.60
Bone, 3 and 50, ground, raw	ton	32.00 —	35.00
Fish scrap, dom., dried, f.o.b. works	unit	3.10 —	3.20
Nitrate of soda	100 lb.	2.55 —	2.60
Tankage, high grade, f.o.b. Chicago	unit	3.10 —	3.20
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	3.50 —	3.75
Tennessee, 78-80%	ton	7.00 —	7.50
Potassium muriate, 80%	ton	33.00 —	33.50
Potassium sulphate	unit	1.00 —	....

Crude Rubber

Para—Upriver fine	lb.	$0.18 —	.18¼
Upriver coarse	lb.	.12¼ —	.12¾
Upriver caucho ball	lb.	.13¼ —	.14
Plantation—First latex crepe	lb.	.15¼ —	.15¾
Ribbed smoked sheets	lb.	.15¼ —	.15½
Brown crepe, thin, clean	lb.	.13¾ —	....
Amber crepe No. 1	lb.	.14½ —	....

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.11 —	$0.11¼
Castor oil, AA, in bbls.	lb.	.12 —	.12¼
China wood oil in bbls.	lb.	.13¼ —	1

Coconut oil, Ceylon grade, in bbls	lb.	.08 —	.08¼
Coconut oil, Cochin grade, in bbls	lb.	.09¼ —	.09½
Corn oil, crude, in bbls	lb.	.11¼ —	.11½
Cottonseed oil, crude (f. o. b. mill)	lb.	$0.10 —	$0.10
Cottonseed oil, summer yellow	lb.	.11¼ —	.12
Cottonseed oil, winter yellow	lb.	.12 —	.13
Linseed oil, raw, car lots (domestic)	gal.	.87 —	.88
Linseed oil, raw, tank cars (domestic)	gal.	.83 —	.84
Linseed oil, boiled, in 5-bbl lots (domestic)	gal.	.92 —	.93
Olive oil, denatured	gal.	1.15 —	1.17
Palm, Lagos	lb.	.07⅞ —	.07
Palm, Niger	lb.	.06⅛ —	.06
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.09½ —	.10
Peanut oil, refined, in bbls	lb.	.12½ —	.12¾
Rapeseed oil, refined in bbls	gal.	.84 —	.85

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Tennessee Coal, Iron & Railroad Co. is perfecting plans for the early erection of a new foundry for the production of steel castings at the plant of its subsidiary organization, the Chickasaw Shipbuilding & Car Co., Fairfield, Ala. The company is also planning for the remodeling of the foundry at its Ensley, Ala., works, with extensive increase in capacity for the production of iron castings, ingot molds, etc.

California

PITTSBURG — The Pioneer Rubber Co., 68 Sacramento St., San Francisco, will soon call for bids for the erection of a 1-story building here, 80x200 ft., estimated to cost about $150,000, including equipment. Benjamin G. McDougall, 381 Bush St., San Francisco, is architect.

OAKLAND—The Pennzoil Co., Oil City, Pa., affiliated with the Penn-American Refining Co., has acquired property, totaling about 2 acres on Powell St., near San Pablo Ave., for the construction of a new plant for Pacific Coast Service. Plans will be prepared at an early date.

Connecticut

HARTFORD—The Skat Co., Francis Ave., manufacturer of soaps, soap powders, etc., will call for bids at once for the erection of a 1-story plant addition, 46x61 ft. Plans have been prepared by F. C. Walz, architect, Hartford.

MANCHESTER—The Oxford Soap Co. will soon commence the erection of its proposed new plant on Hilliard St., to be 2- and 3-story, 70x150 ft. Plans have been completed. The structure will be used as an addition to its existing works.

Illinois

ROCK ISLAND—The Service Rubber Co., 401 Central Trust Bldg., is taking bids on a general contract for the erection of a new 3-story plant, 60x200 ft., estimated to cost about $100,000, including machinery. Carrin & Horn, 311 Safety Bldg., are architects. J. T. Crowley is one of the heads of the company.

Indiana

ST. MARYS—Joseph Entwhistle has leased the former plant of the Terre Haute Vitrified Brick Co., St. Marys, near Terre Haute, and is organizing a company to operate the property. The plant has been closed down for about 2 years past. The new owner will make a number of improvements, and will remodel the works for the production of face brick, instead of paving brick as heretofore produced. It is planned to commence operations at an early date and develop a maximum production of 40,000 bricks per day.

INDIANAPOLIS—The Majestic Tire & Rubber Co. has acquired a portion of the brewing plant at Crouse and Daly Sts., heretofore owned by the Home Brewing Co., for a consideration of about $32,000. The structure will be remodeled for a new rubber mill.

BIPPUS—The Bippus Tile Co. has been reorganized under the name of the Bippus Clay Products Co., with capital of $55,000, the new company being headed by H. V. D. King, Godhen, Ind., and associates. A tract of 36 acres of land adjoining the present plant has been acquired, and plans are under way for extensive operations. The company will manufacture tile and other burned clay products. John H. Sell, Bippus, is interested in the new organization.

PRINCETON—The Premier Refining Co., a subsidiary of the Consolidated Oil Development Co., recently organized, has work under way on a new gasoline process plant in the Oatsville field, near Princeton. A crude oil plant will also be operated by the company, and plans are now being perfected for the establishment of a distributing plant on site selected at Princeton. C. L. Herber, Terre Haute, is president; and L. C. Nicholson, Indianapolis, vice-president.

Kansas

ARKANSAS—The Moore Refining Co., recently organized with a capital of $1,000,000, has acquired the local oil refinery of the Milliken Refining Co., and has placed the plant in operation. The refinery has a capacity of 2,500 bbl. per day, and tentative plans are under consideration to increase this to more than 5,000 bbl. daily, with the construction of a large extension. George N. Moore, formerly president of the Shaffer Oil & Refining Co., Chicago, Ill., heads the new organization. E. R. Perry and W. R. Layne, both of Tulsa, Okla., are interested in the new company.

WICHITA—The Kansas-Texas Oil Co., a subsidiary of the Kansas-Texas Oil Corp. of New York, has acquired the local refinery and lubricating oil plant of the Derby Oil Co. Possession will be taken on July 1, and extensive operations are planned. The refinery has a rating of 1,800 bbl. per day, and was secured for a consideration of about $100,000. The Derby company is completing the erection of a new oil refinery on an adjoining tract, and will commence production at an early date. This latter plant will have an output of about 5,000 bbl. per day.

Louisiana

ALEXANDRIA—Bonds have been approved in an amount of $110,000, for the construction of a new municipal gas plant. Plans will be prepared at an early date. The City Council is in charge.

Maine

FAIRFIELD—The Keyes Fibre Co., has work under way on enlargements in its local pulp mill. A new conveying system will be installed in connection with other equipment for increased production.

Maryland

TEXAS—The Maryland Calcite Co., P. O. Box 102, recently organized with a capital of $100,000, has plans under way for the erection of a new local plant for the manufacture of whiting, marble flour and kindred specialties. Three 1-story buildings will be constructed, 20x88 ft., 16x20 ft., and 14x20 ft., respectively. The installation will comprise crushing machinery, rolls, elevating equipment, buhr mills, screens, etc., to provide for an initial output of about 100 tons per day. R. L. Lovell is president, and Richard E. Tome, secretary.

BALTIMORE—The Standard Acid Works, Inc., 1150 South Division St., will commence the immediate installation of a new steel tank and auxiliary equipment at its plant.

FROSTBURG — The Frostburg Sewer Pipe Co. is being organized with a capital of $200,000, to construct and operate a local plant for the manufacture of vitrified sewer pipe and affiliated burned clay products. A site for the plant has been selected, including clay properties for raw material supply. It is said that the initial works will cost in excess of $50,000. The Frostburg Commercial Club, T. C. Carrington, secretary, is interested in the project.

Massachusetts

PEABODY—The Wetan Leather Co., Danversport, Mass., has acquired the local plant of the Formal Leather Co., Central St. The structure will be remodeled and occupied by the new owner for the manufacture of a general line of upper leather. It will be used to replace the Danversport plant lately destroyed by fire.

Michigan

LAWTON—The Schlangen Brothers Co., 2435 Irving Park Blvd., Chicago, Ill., manufacturer of machine equipment, etc., has acquired a site at Lawton, for the erection of a new plant, 50x400 ft., for the manufacture of brass products. It is said that the present plant of the company will be removed to the new location in the near future.

LANSING—The Lansing Paint & Color Co., operating at the plant of the Lansing Chemical Co., acquired a number of months ago, will electrify all departments of the works heretofore using steam power, and will abandon the latter type of operation entirely.

CADILLAC—The Cadillac Malleable Iron Co., is completing the erection of a new foundry and will install equipment at an early date. It is planned to commence production at the plant early in the fall, giving employment to about 100 men. J. C. Ford is president, and George T. Mitchell, vice-president.

Nebraska

OMAHA—The Metropolitan Utilities District has plans under consideration for the installation of a new filtration plant at the waterworks, to cost about $600,000, including equipment. Plans will be prepared at once. F. D. Wead is chairman of the board.

New Jersey

YARDVILLE—The Spartan Rubber Co. has been organized with a capital of $100,000, to take over and operate the local plant of the Zee Zee Rubber Co., recently acquired from the receiver by Edward D. Newman, 29 Broadway, New York, N. Y., for $58,000, and who will be vice-president and secretary of the new organization. The plant will be improved in a number of departments and operations resumed at an early date for the manufacture of tires and other rubber products. It is planned to give employment to about 200 men, under a full time production schedule. Arthur Newman is president of the company, and Stanley Newman, treasurer.

NEWARK—The Premier Rubber Co., recently organized, has acquired the factory buildings at 218-24 New St., at Hoyt St., for the establishment of a new plant for the manufacture of rubber products. Equipment will be installed at once and it is proposed to commence production early in August.

DELAIR—The Kieckhefer Paper Co., Thorne St., Camden, has construction under way on its proposed new local plant for the manufacture of paper containers and kindred products. J. W. Kieckhefer is president.

PERTH AMBOY—The Perth Amboy Oil & Terminal Co., First National Bank Bldg., recently organized, has plans nearing completion for the construction of its proposed oil distributing plant on site, lately acquired at Woodbridge, near Perth Amboy. The new plant will consist of a number of buildings, estimated to cost $130,000, including tanks, machinery, etc. It will give employment to more than 150 men. Luke Mooney is president, and John E. Toolan, secretary.

New York

AMBOY—The Syracuse Pottery Co., 711 East Division St., Syracuse, has awarded a contract to Grassman, Jackson & Hunter, South Crouse Ave., Syracuse, for the construction of a new plant at Amboy. It will be 1-story, 40x140 ft., including kiln department. Work will be commenced at once.

North Carolina

WINSTON-SALEM—The John Reich Co., manufacturer of paints, varnishes, etc., has plans under way for the construction of a 2-story plant, 60x75 ft., to replace its factory recently destroyed by fire.

Ohio

BELLAIRE—The C. L. Dorer Foundry Co. has awarded a contract to the Riverside Bridge Co., Martins Ferry, O., for the construction of a 1-story addition to its foundry, 32x60 ft. C. L. Dorer is president and general manager.

NEWTON FALLS—The Newton Steel Co. has awarded a contract to the McClintic-Marshall Co., Pittsburgh, Pa., for the construction of a new plant addition, estimated to cost close to $750,000, including machinery. It will be equipped as a sheet mill.

Oklahoma

ARDMORE — R. H. Harris & Son, Ada, Okla., have plans in progress for the construction of a local brick-manufacturing plant, with capacity of 20,000 bricks daily.

Pennsylvania

GLASSMERE—Fire, June 19, destroyed a portion of the local plant of the Allegheny Plate Glass Co., with loss estimated at about 50,000, including equipment.

destroyed structure was 3-story, 50x100 ft., and was used primarily for a clay pot department. It is planned to rebuild at once.

PHILADELPHIA — Thomas Savill's Sons, 1310 Wallace St., manufacturers of pipe, etc., have awarded a contract to Seeds & Steinmetz, 1101 Divinity Pl., for the construction of their proposed 2-story foundry, 52x60 ft., at 635-37 North Watts St.

PITTSBURGH — Fire, June 21, destroyed two buildings at the plant of the Ball Chemical Co., Butler Plank Road, Wittmer district, with loss approximating $200,000, including equipment. The company manufactures paints, varnishes, etc. Its headquarters are in the Fulton Bldg. It is said that the plant will be rebuilt at an early date.

PHILADELPHIA—The Shingle Leather Co., 315 Vine St., has taken title to property at 54th St. and Grays Ferry Ave., 120x300 ft., to be used as a site for the construction of a 1-story plant, estimated to cost $50,000, for which contract recently was awarded to the Bowden Construction Co., 1713 Sansom St. Work will be placed under way at once.

NEW OXFORD—The Susquehanna Casting Co., Wrightsville, Pa., manufacturer of iron and steel castings, has commenced the construction of a new local foundry on property recently acquired.

South Carolina

GREENVILLE—The city Water Commission is planning for the installation of a new chlorinating plant at the municipal water works. W. C. Beecham is chairman.

Tennessee

KNOXVILLE—The Davis Mfg. Co. has plans in progress for the construction of a 4-story and basement plant on Asylum Ave., to be equipped for the manufacture of extracts. It will cost close to $250,000, with equipment. Grover C. Davis is president.

COLUMBIA — The American Agricultural Chemical Co., 2 Rector St., New York, N. Y., is reported to be planning for the construction of a new plant here, for the manufacture of commercial fertilizers, with capacity of about 150 tons per day.

Texas

WICHITA FALLS — The Texhoma Oil & Refining Co. has acquired the local oil-refining plant of the Bankers' Refinery Co., and will place the works in operation at once. It is proposed to develop an output of close to 4,000 bbl. per day.

Virginia

FREDERICKSBURG — The Natural Tanning Extract Co. has taken over the local dye plant of Walter Wilson & Brothers, and will operate the works for the manufacture of tanning extracts, including sumac, etc. The companies are affiliated. Walter Wilson is president of both organizations.

West Virginia

NITRO—The Charleston Paper Mfg. Co., Charleston, W. Va., has plans nearing completion for the establishment of its proposed paper-manufacturing plant on local property, improved with a number of buildings, lately acquired. The works will be remodeled; the main structure will be 60x560 ft. The project will involve about $400,000, with machinery. Charles G. Hartje, Steubenville, O., is president.

Canada

KIMBERLEY, ONT.—The Consolidated Mining & Smelting Co., Ltd., Montreal, Que., will commence the immediate erection of its proposed new concentrating plant on site near Kimberley, estimated to cost in excess of $1,000,000. It will be electrically operated in all departments and will have an initial capacity of close to 1,500 tons per day.

New Companies

THE ENGLISH CHEMICAL CO., Paterson, N. J., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are Fred G. Parker, Henry Benkes, Jr., and Henry Smith, 297 Main St., Paterson.

THE BLACK-IRON STOVE POLISH CO., Lawrence, Mass., has been incorporated with a capital of $70,000, to manufacture polishes and kindred products. Alvin L. Hofmann is president; and Richard P. Fiedler, 40 Swan St., Methuen, Mass., treasurer.

THE NONPAREIL GELATOID PRODUCTS CO., New York, care of A. G. Scheer, 149 Broadway, representative, has been incorporated with a capital of $10,000, to manufacture imitation celluloid and other composition products. The incorporators are M. Hicks and J. A. Pierce.

THE J. M. STOEVER CO., Chester, Pa., is being organized under state laws to manufacture chemicals and chemical byproducts, extracts and kindred specialties. Application for a state charter will be made on July 17. The company is represented by Kingsley Montgomery, Law Bldg., Chester.

THE FARMERS' COTTON OIL MILL & GINNERIES CO., Shellman, Ala., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are W. J. Oliver, J. M. Bell and W. R. Terry, all of Shellman.

THE STRATFORD RUBBER MFG. CO., 1736 South Michigan Ave., Chicago, Ill., has been organized under state laws to manufacture rubber products. The incorporators are Paul P. Harris, Fred W. Reinhardt and John A. Russell.

THE ACID RECOVERY CO., Brooklyn, N. Y., care of the United States Corporation Co., 65 Cedar St., New York, has been incorporated with a capital of $150,000, under Delaware laws, to manufacture acids and affiliated products. The incorporators are L. Lieberman, Walter K. Simonson, Brooklyn; and Otto Mantius, Englewood, N. J.

THE AMERICAN ASBESTOS MFG. CO., 336 Wayne St., Jersey City, N. J., has been incorporated with a capital of $50,000, to manufacture asbestos products. C. J. Skinner is one of the incorporators.

THE IRONIDE FOUNDRY, INC., Ware, Mass., has been incorporated with a capital of $50,000, to manufacture iron and other metal castings. Edward A. Johnson is president; and Stephen R. Jones, 220 North Main St., Brockton, Mass., treasurer.

THE BLUEBIRD OIL CO., Delmar (Albany County), N. Y., care of H. B. Casey, Albany, N. Y., representative, has been incorporated with a capital of $12,000, to manufacture oil products. The incorporators are J. O. Chamberlain, L. Arnold and E. C. Haswell.

THE COMBINED PRODUCERS OIL CORP., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $3,000,000, to manufacture petroleum products.

THE FRENCH COMPACT PRODUCTS CORP. OF AMERICA, Providence, R. I., has been incorporated with a capital of $10,000, to manufacture composition products. The incorporators are E. R. and Charles Z. Alexander, and Francis A. Cullen, all of Cranston, R. I.

THE A. C. RUBBER CO., Elyria, Ohio, has been incorporated with a capital of $10,000, to manufacture rubber products. The incorporators are W. R. Huntington and J. W. Dewhurst, both of Elyria.

THE PIONEER PETROLEUM CORP. OF AMERICA, El Dorado, Ark., has been incorporated with a capital of $1,000,000, to manufacture petroleum products. The incorporators are James A. Clark, George Irving and L. C. Harper, all of El Dorado.

THE RENNIEBUT RUBBER CO., 8 Van Wagenen St., Newark, N. J., has filed notice of organization to manufacture rubber products. The company is headed by Charles H. Tisserand, 177 Broad St., Newark.

THE KITTANNING GREY BRICK CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $100,000, to manufacture pressed brick and other burned clay products, with plant in Pennsylvania.

THE STANDARD CHEMICAL PRODUCTS CO., Hoboken, N. J., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are A. Lincoln Lavine, Henry Ruegg, Jr., and Louis L. Grombacher, 1021 Grand St., Hoboken.

THE SIMMONS INK CO., Indianapolis, Ind., has been incorporated with a capital of $5,000, to manufacture ink and kindred products. The incorporators are Richard Budlong, Paul Simmons and Earl Stansbury, all of Indianapolis.

THE AMERICAN ADAMITE CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws, with capital of $1,000,000, to manufacture special steel products.

THE LIMESTONE FERTILIZER & BALLAST ROCK CORP., Golconda, Ill., has been incorporated with capital of $150,000, to manufacture fertilizers and affiliated products. The incorporators are John O. Kluge, Thomas H. Lackland, and John B. King, 1000 Peoria Life Bldg., Peoria, Ill.

THE SUNSET RUBBER CO., Everett, Wash., has been incorporated with a capital of $150,000, to manufacture automobile tires and other rubber products. The incorporators are C. E. Powley, W. C. Cloud and William Sheller, 326 Stokes Bldg., Everett.

THE MEADOW OIL CO., Newark, N. J., has been incorporated with a capital of $25,000, to manufacture oil products. The incorporators are Armond R. Schorner, Richard Betterman and George N. Aubertin, 196 Market St., Newark.

THE SOUTHERN & WESTERN GLASS PRODUCTS CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., has been incorporated under state laws with a capital of $2,500,000, to manufacture glass caskets and other glass products.

MARQUETTE & CO., INC., Haverhill, Mass., has been incorporated with a capital of $50,000, to operate a local tannery. George H. Marquette is president; and Oliver C. Frost, 66 Fountain St., Haverhill, treasurer.

THE WOOD COUNTY COTTON OIL CO., Mineola, Tex., has been incorporated with a capital of $56,000, to manufacture oil products. The incorporators are R. Bergfeld, W. W. Perry and H. W. Meredith, all of Mineola.

THE PYORHINE CHEMICAL CO., Seattle, Wash., has been incorporated with a capital of $40,000, to manufacture chemicals and chemical byproducts. The incorporators are David T. Lloyd and S. Ross Parker, 1603 Terry Ave., Seattle.

THE PLEASANTVILLE CONCRETE PRODUCTS CO., Pleasantville, N. J., has been incorporated with a capital of $50,000, to manufacture cement and concrete specialties. The incorporators are A. J. Milliken, Philip S. and Carlton Godfrey, 317 Guarantee Trust Bldg., Atlantic City, N. J.

THE HANDY GLASS CO., Philadelphia, Pa., care of the Corporation Guarantee & Trust Co., Land Title Bldg., has been incorporated under Delaware laws, with a capital of $200,000, to manufacture glass products.

THE CAPITAL FIBRE CORP., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., has been incorporated under state laws, with capital of $2,000,000, to manufacture fiber products.

THE ERNFINE TRADING CORP., New York, N. Y., care of Latson & Tamblyn, 66 Broadway, representatives, has been incorporated with a capital of $75,000, to manufacture fire prevention chemicals. The incorporators are W. N. Wilkinson, J. T. Barry and W. N. Wilkinson.

THE TROGIN PRODUCTS CO., 244 Wayne St., Jersey City, N. J., has filed notice of organization to manufacture chemicals and chemical byproducts, drugs and kindred products. The company is headed by H. George Tilleman and L. A. Sista.

THE CLAYTON OIL & REFINING CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $850,000, to manufacture refined petroleum products.

THE PAN AMERICAN SOAP CO., Brooklyn, N. Y., care of Louis Horwitz, 772 Broadway, Brooklyn, representative, has been incorporated with a capital of $5,000, to manufacture soaps and kindred products. The incorporators are B. Gerber, M. Klaits and E. Schneider.

THE CENTURY CHEMISTS, INC., Room 1224, 202 South State St., Chicago, Ill., has been incorporated with a nominal capital of $1,500, to manufacture chemical specialties and preparations. The incorporators are F. King, P. Stolz and H. H. Sharpe.

THE KY-IND-O OIL CORP., Lexington, Ky., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are S. G. Smelser and George N. Snyder, both of Richmond, Ind., and Z. O. Avry, Lexington.

THE MINEOLA TILE MFG. CO., Mineola, L. I., care of Seabury, Seaman & Gehrig, Hempstead, L. I., representatives, has been incorporated with a capital of $50,000, to manufacture tile and other ceramic products. The incorporators are E. Schmidt, A. A. Lein and E. J. Armstrong.

THE VITROLITE PRODUCTS CO., 218 North Union Ave., Chicago, Ill., has been incorporated with a capital of $100,000, to manufacture composition products. The incorporators are F. J. and Thomas C. Downs, and J. F. Hardin.

THE SIX MEDALS CHEMICAL CO., New York, N. Y., care of J. M. Frost, 174 Rivington St., representative, has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts. The incorporators are H. Kaufman and L. Perlstein.

THE P. T. L. MFG. CO., 219 Ave. E. Bayonne, N. J., has filed notice of organization to manufacture chemical specialties,

disinfectants, etc. Isadore Hollender heads the company.

THE BLOOD RIVER OIL CO., care of the Delaware Registration Trust Co., 900 Market St., Wilmington, Del., representative, has been incorporated with a capital of $300,000, under state laws, to manufacture petroleum products.

THE OTIS-GRAY CO., 208 South La Salle St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture petroleum and other oil products. The incorporators are L. L. Losey, Max Haleff and D. D. Stansbury.

THE MARYLAND CALCITE CO., Texas, Md., has been incorporated with a capital of $100,000, to manufacture lime and affiliated products. The incorporators are Raymond L. Lovell, Richard E. Tome and Palmer R. Nickerson, all of Texas, Md.

THE AMALGAMATED PETROLEUM & REFINING CO., New York, N. Y., care of Leonard E. Wales, Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $1,500,000, to manufacture refined petroleum products. The incorporators are Martin V. McTuigg, Arthur W. White and George L. Barney, New York.

THE LANE RUBBER CO., INC., Norwich, Conn., has been incorporated with a capital of $50,000, to manufacture rubber products. The incorporators are George E. Hall, R. E. and C. E. Lane, 46 Hamilton Ave., Norwich.

THE ALBEMARLE SOAPSTONE CO., Esmont, Va., has been incorporated with a capital of $150,000, to manufacture commercial soapstone products. H. P. McCary is president; and E. W. Scott, Jr., secretary, both of Esmont.

THE NORTHWEST REFINING CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated with a capital of $1,300,000 under Delaware laws, to manufacture petroleum products.

THE SWANSON OIL CORP., East Peoria, Ill., care of William J. Peck, Jefferson Bldg., Peoria, Ill., representative, has been incorporated with a capital of $25,000, to manufacture refined oil products. The incorporators are Otto B. and Edward A. Swanson, and Oakley Marlott.

Industrial Developments

RUBBER—The B. F. Goodrich Co., Akron, O., has advanced production from 18,000 to 22,000 tires a day at its local plant.

All tire-manufacturing plants at Columbus, O., have been placed on a capacity basis, under two-shift operation.

The Goodyear Tire & Rubber Co., Akron, O., has increased production to a maximum of 32,000 tires a day at its Akron, O., California and Canadian plants; the output of the first noted factory is now rated at 26,000 tires daily.

The Republic Rubber Corp., Youngstown, O., has increased production from 1,500 to 1,800 tires a day at its local plant. The mechanical rubber goods department is running full, and orders in this branch are said to be in excess of output.

The Firestone Tire & Rubber Co., Akron, O., has advanced operations to a maximum of 25,000 tires a day at its local plant.

The rubber specialty departments of mills at Akron, O., have developed the heaviest production during the past few weeks than evidenced for more than a year past. A number of plants are working an extra night shift.

The Continental Rubber Co., Torreon, Mex., is curtailing operations at its local plant owing to the unsatisfactory labor conditions in this district and the low price of crude material.

The Miller Rubber Co., Akron, O., has increased manufacture from 6,500 to 7,500 tires per day.

CERAMIC—Clay products plants at Irondale, near Salineville, O., are increasing production and making additions to their working forces. The McClane Fire Brick Co. is operating both of its local plants at capacity; the Benfield Clay Co. has advanced production to 100 per cent, giving employment to about 75 men; the East Ohio Sewer Pipe Co. is running full at its No. 2 plant, giving work to a regular quota. The No. 1 plant of the last noted company is still idle, but is expected to resume in the near future.

All brick manufacturing plants in Texas are running at maximum capacity, according to a report made at the recent annual meeting of the Texas Brick Manufacturers' Association, and the present year is expected to be the greatest in the history of the state industry.

IRON AND STEEL—The Bon Air Coal & Iron Co., Nashville, Tenn., has resumed operations at its Goodrich blast furnace, following a suspension since November, 1920. It is planned to develop capacity at an early date.

The Crucible Steel Co., Pittsburgh, Pa., is running at from 70 to 80 per cent of capacity at its different plants. Each month is showing an improvement over the previous one, it is stated.

The United Alloy Steel Co., Canton, O., is operating at capacity at its heat-treating department and cold-drawing mills. All bar mills are in service, and production is being advanced in the open-hearth department. The company is said to have orders on hand for at least two months' maximum capacity.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., is planning to blow in its No. 4 stack at Bessemer, Ala., at an early date. It will produce foundry pig iron.

The Sharon Steel Hoop Co., Youngstown, O., will blow in its blast furnace at Lowellville, O., at once, making the sixth unit to be placed in service by the company since the commencement of the coal strike. The Lowellville furnace will be used for supplying the local mills.

The Robesonia Iron Co., Robesonia, Pa., has placed its recently relined furnace in blast, following an idleness of several months. Employment will be given to about 150 men, with the unit operating on a basis of 250 tons per day. An advance of 10 per cent has been made in wages at the plant.

The Midvale Steel & Ordnance Co., Philadelphia, Pa., is now operating at about 75 per cent of normal at its plants.

Mudge & Co., operating a blast furnace at Sharpsville, Pa., has increased the capacity of the plant to about 400 tons a day. Four hot blasts are now being added.

The Republic Iron & Steel Co., Youngstown, O., is planning to light another furnace at an early date for the production of Bessemer iron. Closely following, it is expected to resume at the steel-making mills, which have been idle for a number of months.

The Eastern Steel Co., Pottsville, Pa., is resuming operations in all departments of its plant, with the exception of the open-hearth furnaces. The plant has been on a curtailed basis for the past 18 months.

The Charcoal Iron Co. of America, Ashland, Wis., is resuming operations at three of its four plants, including the local mills and works at Newberry and Manistique, Mich. The Ashland plant has been improved and extended, and a new 175-ft. stack built. It will run on pig iron- charcoal, alcohol and byproducts, giving employment to about 600 men. The blast furnace department will engage a quota of 150 operatives. The plant of the company at Boyne City, Mich., is still shut down, and is not expected to resume until later in the year.

METALS—The Shasta Zinc & Copper Co. has resumed operations at its plant at Winthrop, Cal., giving employment to about 200 men. As soon as conditions warrant, operations will be advanced to maximum, totaling close to 300,000 lb. of copper, and 2,000,000 lb. of zinc oxide per month.

The Canada Copper Corp. is considering the resumption of production at its plant at Princeton, B. C., early in August. The mill has a capacity of about 2,000 tons a day.

The Eureka Metallurgical Co., Salt Lake City, Utah, is completing a new test mill on site south of the city, and plans to place the unit in service at an early date.

The International Smelting Co., Salt Lake City, Utah, has resumed operations at its Utah plant, following a suspension for more than a year past. One of the copper reverberatory furnaces has been blown in, to operate with a daily capacity of approximately 300 tons. A number of lead furnaces will be placed in service, to develop an output of 400 tons a day of lead ores and concentrates.

MISCELLANEOUS—The Pennsylvania Glass Sand Co. has resumed operations at its Dawson Works, Vineyard, Pa., following a suspension for a number of months.

The Lehigh Portland Cement Co., New Castle, Pa., has placed its three local mills on a capacity basis, giving employment to an increased working force.

The Atlas Portland Cement Co. is maintaining operations at its large mill at Northampton, Pa.

The General Leather Co., Newark, N. J., specializing in automobile leathers, will soon commence production in its new local plant, which has been in course of construction for some time past. The structure forms a complete duplicate plant unit, and is expected to double the output.

Capital Increases, Etc.

THE COMMERCIAL SOLVENTS CORP., Terre Haute, Ind., manufacturer of alcohol solvents, etc., is disposing of a stock issue of $1,800,000, the proceeds to be used for general expansion. P. G. Mumford is president.

THE CHICAGO BRICK CO., 38 South Dearborn St., Chicago, Ill., has filed notice of increase in capital from $10,000 to $250,000, for expansion.

THE SANIWAX PAPER CO., Kalamazoo, Mich., has filed notice of increase in capital from $20,000 to $215,000, for general expansion.

THE RACINE HORSESHOE TIRE CO., Racine, Wis., manufacturer of automobile tires, etc., is disposing of a bond issue of $300,000, the proceeds to be used for general expansion. J. B. Lawrence is president.

THE INDEPENDENT PAPER MILLS, INC., 68 35th St., Brooklyn, N. Y., has filed notice of increase in capital from $50,000 to $100,000.

THE UNITED GLUE CO., Indianapolis, Ind., has filed notice of dissolution under state laws.

THE WHITTEMORE GLASS CO., Dunbar, W. Va., manufacturer of window glass, is arranging for an increase in capital to $500,000, for general expansion. A. P. Whittemore is president.

Grayson Stetson has been appointed receiver for the TEMPLER LEATHER CO., Salem, Mass.

THE COLLOIDAL PROCESS PAINT CO., Baltimore, Md., has arranged for an increase in capital of $100,000, the proceeds to be used for general expansion, at the same time filing notice of change of name to the National Bitumens Corp.

THE MISSOURI PORTLAND CEMENT CO., St. Louis, Mo., has arranged for a bond issue of $2,000,000, a portion of the proceeds to be used for expansion.

THE LION OIL & REFINING CO., Kansas City, Mo., has filed notice of increase in capital from $450,000 to $750,000.

THE FIRESTONE TIRE & RUBBER CO. OF CANADA, LTD., Hamilton, Ont., a subsidiary of the Firestone Tire & Rubber Co., Akron, O., is disposing of a bond issue of $1,500,000, a portion of the proceeds to be used in connection with the erection of a new local plant, general operations, etc.

THE CENTRAL SHALE OIL CORP., Highland Blvd., Pittsburgh, Pa., has filed notice of increase in capital from $1,000,000 to $1,500,000.

THE WAUKEGAN CHEMICAL CO., Waukegan, Ill., has filed notice of increase in capital from $10,000 to $25,000, for general expansion.

The foundry and property of the EMERY STEEL CASTINGS CO., South Charles and Hanover Sts., Baltimore, Md., will be sold by Albert R. Stuart, trustee in bankruptcy.

THE MESABI IRON CO., 25 Broad St., New York, N. Y., a Delaware corporation, has filed notice of increase in capital from $53,000,000 to $103,000,000, for general expansion.

THE LION TIRE & RUBBER CORP., Lafayette, Ind., has filed notice of increase in capital from $500,000 to $700,000, for general expansion.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold a summer excursion meeting to Rochester, Montreal, Ottawa, Kingston, Toronto, Hamilton, Niagara Falls and Buffalo, Aug. 13-19.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer, but will resume them in October.

Demand on Chemical Foundation For Return of German Patents

WHEN a bomb explodes, either literally or figuratively, a close observer will at first be conscious only of a series of scattered and disconnected impressions. Afterward a coherent story comes out of the experience. That is exactly what happened in the chemical industry when President HARDING'S letter to the Alien Property Custodian was published last Saturday. The President directed him to demand the return of all patents, trade marks, etc., sold to the Chemical Foundation, Inc., and to act upon the advice of the Attorney-General in carrying out the instructions. The Attorney-General has since subpœnaed the Foundation's books and papers before a grand jury in Washington.

The first reactions among those interested in the chemical industry and the Chemical Foundation were rather vague and indefinite. How much politics was involved in the President's order? What agencies had succeeded in thus crystallizing sentiment against the Chemical Foundation? Had that organization been guilty of anything not legally or morally straight in its transactions? What would be the effect of the President's order on the chemical industry, particularly the dye industry of the country? Were German propaganda and influence, as represented by dye importers, in any way responsible for persuading Washington to take this step? These and other questions flashed through the mind without apparently throwing any light on the situation. But out of all the speculation that has been rife we may now single a few outstanding facts and probabilities, and on them base with some degree of assurance a reasonable prediction.

The basis of the President's order is that "it appears that the sale was made at so nearly a nominal sum that there is reason to believe that this government has not faithfully observed the trust which was implied in the seizure of this property." No one can find fault with this basis for the demand. Under the trading with the enemy act, the Alien Property Custodian seized enemy property and held it in trust for its owners. Presumably that property or its value was at some time to be returned to those from whom it was seized. If it was sold, the sale presumably should have been at a price commensurate with the value of the property. The President, therefore, cannot be criticised for desiring "to maintain the sacred character of the trust to which the Alien Property Custodian is committed by the law." The natural consequence is, to use the President's own words, "that full investigation becomes a public duty."

By all means let's investigate and let the fullest publicity be given to the investigation. If, as in the case of Senator KING'S investigation of the dye industry, the original charges prove to be fictitious, the Chemical Foundation will be more firmly established than ever. If, on the other hand, it can be proved that more should have been paid for these patents than was paid under the direct orders and with the full approval of the government, then let a proper adjustment be made. But before any such settlement is made, and particularly before any charges of corruption and unfairness are entertained let all the facts be known. The Chemical Foundation has been under fire before now. Its scheme of organization, its methods of conducting business, its resources and the disposition of its income have been the subject of public inquiry. But if we were the Chemical Foundation we would not only welcome but would now demand a clean-cut investigation.

There can be no doubt, however, that behind the President's order there is some yielding to political clamor. Our Washington correspondent says that while there is no tendency to charge ulterior motives to the Administration, it is nevertheless felt that the Attorney-General, who has been subject to repeated attacks in Congress, welcomes any action that will serve as a smoke screen to divert from him the unwelcome attention he has been receiving. Further, there is in Congress a group of partisans, mainly Republicans but with some Democratic adherents, who would like nothing better than to see former Attorney-General PALMER and former Alien Property Custodian GARVAN skinned out of their political hides. Finally, there is the ever-present animosity of dye importers whose views sometimes find favor in strange political quarters.

But what will be the ultimate result and the intervening consequences of the President's order? It may almost be set down as a certainty that the Chemical Foundation will never return or be obliged to return the property it bought. The men who organized it and the chemical companies who are stockholders in it have as good business and legal minds as there are in the country, and it is not likely that they would have invested capital or taken licenses on patents if the business were on so flimsy a basis as to be summarily overthrown. As to the intervening consequences, the legal battle that will follow the demand of the Alien Property Custodian is certain to be long and tedious, for there is no better legal talent in the country than will be arrayed against the Attorney-General in this case.

It is, of course, unfortunate that the President issued his order at this time, because it may seriously affect matters of great importance to the chemical industry now pending in Congress, notably the dye embargo. As for production under the licensed patents, however, it seems unlikely that this will be adversely affected, because arrangements undoubtedly can be made for licensees to continue manufacture under a court order for periodical accounting. Temporary disturbance seems inevitable, but in the end we hope for a clean-cut verdict—a vindication or a conviction.

"Seein' Things at Night" In Our Patent System

EVER since the war revealed the deplorable dependence of our organic chemical industries, notably the making of dyes, Congress has made recurring attempts to modify our patent system by compelling patentees to work their patents in the United States within a period of 2 to 5 years on pain of granting licenses to others who would put them into productive operation. The motive behind these various proposals has been to prevent foreigners from patenting their inventions in the United States and then operating them in their own countries and exporting the products to America.

It is an old bugaboo—this fear of foreign brains and ingenuity—and one that will not be laid low by the proposed compulsory working and compulsory licensing amendments to our patent law. England has experienced and survived the same fears. The United States enacted a compulsory working clause in 1832, but repealed it in 1836. Since then attempts to enact similar legislation have been made by OLDFIELD in 1912, PAIGE in 1915 and STANLEY in 1921 and 1922.

Senator STANLEY has been particularly persistent in his efforts. His first bill, in 1921, proposed to compel *foreigners* who patented their inventions in the United States to put them "in operation so as to result in actual production" in this country within a period of 2 years from the date of issue, failing which the United States would reserve the right to license anyone for purposes of domestic manufacture. This bill was invalid because it violated the International Convention for the Protection of Industrial Property, to which the United States is a party and which has been interpreted to mean that any country which is a party to the Convention cannot discriminate against foreign nationals of Convention countries. So Senator STANLEY redrafted his bill to provide that "*any* patent . . . shall contain a proviso to the effect that if such patent . . . is not worked or put in operation so as to result in actual production in the United States . . . within a reasonable time from the date of its issue . . . the United States reserves the right to license any person or persons for purposes of manufacture in the United States." This proposal aroused considerable opposition and on April 20, 1922, Senator STANLEY proposed a further amendment providing in effect that if a United States patentee fails to work his invention in this country within 2 years of the issuance of his patent, and if it is worked in a substantial manner in a foreign country, he can be compelled, on the petition of any reputable American citizen or business organization brought in the U. S. Circuit Court of Appeals, to grant a license to the petitioner upon equitable terms.

We regard this proposal as pernicious regardless of its various legislative forms, and are firmly of the opinion that if enacted into law it would, in the long run, have a baneful influence on American chemical industry. It is true that the Stanley bill apparently has received some substantial support from the Manufacturing Chemists Association, the American Institute of Chemical Engineers, and lately from the American Chemical Society. But we think it is fair to point out that this support comes from laymen and not from those who are most familiar with patent procedure. Further, that most of the support is due to the activities of Mr. HENRY HOWARD, whose energy and determination we admire, but with whom we are obliged to differ on this question. An imposing array of testimony against the measure has been collected and published by the American Patent Law Association giving almost indisputable proof of the futility and folly of the bill. The reader will also find on another page in this issue a thoughtful analysis of the consequence of compulsory licensing, prepared by Dr. D. B. KEYES.

Incidentally, the support apparently given by the American Chemical Society does not carry conviction. The action was taken by the Committee on National Policy in opposition to the advice and opinion of the society's Patent Committee. It was reported editorially under the misnomer "Patent Progress" in the June issue of the *Journal of Industrial and Engineering Chemistry*. Reading between the lines, one may conclude that the editor had but little heart for this particular job, for he wrote a halting and apologetic defense of the action of the Committee on National Policy in overriding the more expert advice of its Patent Committee. The chairman of the latter, Mr. E. J. PRINDLE, naturally resigned. The editor further was misled into stating that the STANLEY bill as now amended "applies only to American patents which are also taken out in foreign countries (less than 10 per cent)." Such is not the case. Senator STANLEY'S latest amendment provides that "2 years after issuance of *any* United States patent . . . if it is shown that the invention covered by such patent is being worked in substantial manner in a foreign country, and that the owner thereof has failed to work it in the United States . . . then on the petition of any reputable American citizen, corporation or partnership . . . the court shall order a non-exclusive license granted to the petitioner." The wording is so clear as to preclude misunderstanding, and the proponents of the measure use a specious argument in claiming that the bill applies only to American patents which are also taken out in foreign countries. It applies to *any* American patent. Yours, for instance!

Isn't it true that fear of the foreigner, and particularly the German dye chemist, is at the bottom of this move? Isn't it the purpose to erect another artificial barrier like the tariff or the dye embargo? No voice has been raised louder than ours in behalf of an American organic chemical industry. But in all the effort that has been made to obtain a protective tariff, even an embargo, for the dye industry of this country it has been clearly recognized that time is the essential element to permit us ultimately to meet foreign competition. It has been our boast that we have the brains, the ability and the materials. All we have asked is time in which to solve our problems, and it has been assumed that we would work out our own salvation.

But we cannot always support a spoon-fed industry. Some time we must quit playing with palliatives. Some time we shall have to stop nursing the industry along with business nostrums. Sooner or later we must depend upon research and development, and these will not be fostered by the Stanley bill in any of its forms. Under the Stanley bill industrial research will wane because it will be cheaper to take licenses; chemical education will not thrive because there will be no demand for chemists; the poor inventor will become extinct because corporations looking for licenses can easily bring him to terms; and as for the national defense, we shall be quite at the mercy of the nations that conduct research and from which we take licenses. In short we shall develop a fine case of fatty degeneration of industry in the United States.

In our judgment the Stanley bill is not only per-

nicious but it is short-sighted and futile. It is looking for something for nothing. Instead of indorsing it our chemical industry should oppose it; and as for the War Department, Secretary WEEKS will be well advised to turn his attention to organized and continuous research and see that the Chemical Warfare Service is supplied with adequate funds for the purpose.

Let's quit "seein' things at night" and go to work! Let's quit breaking up technical organizations and start on a campaign of supporting chemists and research. Let's quit worrying about the other fellow and do some thinking on our own account. Let's quit tinkering with the patent system and make use of a plan that, with all its faults, has developed and fostered the inventive ingenuity of the American people. Compulsory working or compulsory licensing will never foster a dye industry or any other chemical industry in this country.

"Blue" Gas for Heating Coke Ovens And Other Industrial Furnaces

IT HAS been customary to heat coke ovens with a portion of the gas driven off from the coal treated in them. In some cases use is made of the lean-gas produced in the latter portion of the carbonizing period, in others a portion of the run-of-oven gas is used. But in either case only about half of the total gas output is available for use elsewhere in the plant or for sale. In fact, this "surplus" is often much less than half the total and rarely exceeds 60 per cent of the production.

As a consequence of this oven-heating practice, there has been little flexibility in coke-oven installations with respect to the ratio of yields of coke and of gas. Some variation is possible by increasing or decreasing the coking time, but the change in the ratio is not large. The newer idea, which has been applied in a number of plants recently, has been to heat the ovens with producer-gas or blue-gas made in outside generators. When operating on this scheme all of the oven-gas can be considered "surplus," or a part of it may be used for heating the ovens, as conditions may determine.

Where there is a ready market at a good price for practically all the gas made in the coke oven, this separate system of heating is of great importance. And in localities where the controlling product from the ovens is really gas, because this is used in public utility distributing systems, flexibility in gas output relative to coke production is of greatest importance. This has been a question of great financial concern during the past year or two when the demand for gas in such plants continued about as formerly, but the market for coke was at a very low ebb, in some cases almost nil.

In one or two plants gas producers have been installed to meet this situation, and producer gas is now used for heating the ovens part or all of the time. The use of blue-gas, however—that is, uncarburetted water gas—has under certain circumstances distinct advantages over the use of producer gas. The blue-gas can, if necessary in an emergency, be mixed with coke-oven gas and distributed through the public utility system. Thus the blue-gas generator affords standby equipment for the gas system as well as an agency permitting greater flexibility in the operation of the coke ovens. Moreover, both gas producer and blue-gas generator are coke consumers as well as gas-making devices; thus either serves doubly in the effort to reduce the coke output relative to gas output when this is a desirable end.

The plant of one local company which has met this situation very successfully is described by an article in this issue. The results presented by Mr. O'MALLEY in that article will be of interest to members of the gas industry and coke-oven operators generally. They should also appeal strongly to many chemical industries that have a problem of fuel gas to consider.

Blue-gas is one of the finest industrial fuels. Its manufacture on a small scale is possible either with continuous or intermittent operation of the generator. Industrial application of blue-gas has not been general, but more attention should be given to the possibilities of this very fine fuel. Those who have high-temperature heating problems will do well to study particularly the chart in Mr. O'MALLEY'S article, which shows the advantages of blue-gas.

As It Was In the Beginning?

IT WAS our good fortune to spend our earlier days in a small country town. Without making any invidious comparisons we shall always hold that there can be no better place in which to grow up. There are, however, certain aspects of village life which are not, perhaps, as fine when you have to live through them as they are humorous when you look back upon them.

As a case in point, there was Uncle Billy Palmer. Uncle Billy was our village rich man—the man who owned the most property, paid the largest tax, and, consequently, whose word carried the greatest weight in town meeting. He held, in the eyes of the village, a position of Czar and Grand Pooh Bah rolled into one.

From time to time the even flow of life in our town would be disturbed by an outbreak of typhoid. This was in the days before anti-typhoid inoculation was known and when the means of prevention through sanitation were only in their infancy. After much search, the spread of the disease was, however, traced to the contamination of certain wells and a town meeting was called to see what could be done.

The general opinion of the meeting was that a sewerage system should be installed and estimates were called for from the county engineer. But here the meeting met a snag. Uncle Billy fought the proposition tooth and nail. His father and his grandfather before him, he said, had got along without sewers and he'd be eternally danged if he'd ever stand for such new-fangled notions. To make a long story short, the town got no sewers until Uncle Billy was gathered to his fathers. Health and happiness were compelled to wait on stubborn conservatism and old-fashioned ideas.

This tale holds a lesson for those of us who control the affairs of an age which we like to think of as enlightened and progressive. You will find in this same issue an account of what one company has done toward progress in the manufacture of porcelain. This has been accomplished in spite of the strongest kind of opposition from porcelain men within this company, and under the ridicule and doubt of porcelain manufacturers in general. Since the new system of manufacture has proved successful the general attitude of the industry has been that it may work in that particular plant, but it would never work in any other.

Are those responsible for production methods in the porcelain industry going to be unclebillypalmers and compel progress to await their demise? Or are they going to see the light of a new day of manufacture, and by bringing their methods up-to-date, place themselves in a position to compete with foreign products.

Readers' Views and Comments

The Stanley Patent Bill

To the Editor of Chemical & Metallurgical Engineering

SIR:—On May 13, 1922, the committee on national policy of the American Chemical Society unanimously adopted a resolution stating that the society was "in favor of the principle of the Stanley bill, S. 3410, as amended April 20 (calendar day May 4) 1922." This resolution, I understand, was unanimously opposed by the patent committee of the society. Evidently there is a difference in opinion as to what really is the "principle" back of the Stanley bill.

The resolution adopted at that time also stated that the society suggested that "public welfare and the national defense" be considered of equal importance, if the bill is to be modified. It is important to consider the probable effect on the national defense and the public welfare if the bill should be passed as it now stands.

Briefly the bill states that if two years after an American patent is issued the invention is being worked in a foreign country and not in this country, the inventor must grant a license at reasonable terms to any American who desires it. The terms and the general question are to be decided by a United States Circuit Court of Appeals.

The Effect on Industrial Research

The concern which employs a large staff of skilled research chemists might find it not only cheaper and more practical but also safer to buy from someone else the results of research. This last point needs some explanation.

It has been stated that the bill will affect only those patents for which there are corresponding foreign patents, and it is estimated that this includes only 10 per cent of our patents. This, however, is not the case. The bill makes no mention of a foreign patent, but does state that the invention must be in the process of being worked in a foreign country. In other words, the bill applies to *any* American patent that is not being worked in this country, if for any reason at all it is being worked in a foreign country. There is no reason why an American who wishes to seize an unused U. S. patent should not prevail on some one to work the invention in a foreign country, or do it himself. Under the workings of the Stanley bill the American concern that has employed a large staff of skilled research chemists would discover that the value of the patents produced by their staff had diminished. Some of these patents would probably be seized by competitors. The natural attitude would be to discharge the research staff on buying the results of research work from others and especially from the Germans, who do all they can to foster research.

The Effect on Educational Institutions

Professors and instructors in chemistry are hired by our universities to train young men to satisfy the demand of our chemical industries. Anything which affects this demand will affect the salary and number of professors employed. This bill gives the manufacturer the privilege of buying the results of foreign investigators at a nominal sum. It is quite evident that the manufacturer will not fail to seize this opportunity and the need for American professors and instructors in chemistry will be diminished.

The Effect on Subsidized Research

The chemical manufacturer often pays universities, private institutions and consulting chemists to solve his problems. If he should suddenly find that he could purchase the solution at a lower figure from some foreigner, he would be inclined to do so. Business efficiency would demand it, even though our American research men would suffer. Industrial fellowships would be cut down to a minimum and the demand for American consulting chemists would become less.

The Effect on Government Research

Our own government, which employs a vast number of research workers, may also come to the conclusion that in many instances it will be cheaper to buy foreign ideas and the results of foreign research rather than to maintain large research organizations of its own.

The Effect on the Individual Inventor

The research chemist, inventor and patentee who is not employed by any one else must be considered. His chances of obtaining adequate compensation for his work will be less than ever if the Stanley bill becomes a law. As I have already explained, a corporation can easily bring him to terms advantageous to itself by merely working the invention in a foreign country.

The Effect on the National Defense

The War Department is interested in this bill because it believes there would be a tendency to prevent a foreign country from checking the development of American industries necessary in time of war. It is reasonable to suppose, however, should this bill be passed, that no foreign country would patent or disclose any invention absolutely essential in war. If the War Department is interested in the national defense, it is also interested in fostering chemical and scientific research in this country. Why then is it interested in a bill which will have a tendency to eliminate research in this country and foster it in some foreign country?

The Effect on the Public Welfare

The old bugaboo that German chemists are the finest in the world and no other nationality can successfully compete with them is heard again. One manufacturer believes that within ten years the Germans will be far ahead of the American in chemistry. They most certainly will if we eliminate our research men and pay the Germans to do the work for us.

It is evident to every American chemist that our chemical industry has a marked effect on the public welfare. If the Stanley bill becomes a law, it means that our chemical industry will steadily diminish and the American people will suffer.

Fullers Earth

To the Editor of Chemical & Metallurgical Engineering

SIR:—The article in your issue just received mentions incidentally that fullers earth absorbs basic dyes. There is a practical application of this property in the manufacture of "lime green," certain qualities of the English earths, generally the cheaper ones, giving superior results to the German "green earth" formerly used as the basis. The colored paste after absorption of the brilliant green tends to dry hard, but this is counteracted by admixture of the cheaper calcium sulphate. This admixture makes the color from all "green earths" I have tried go dull; with a suitable fullers earth it remains bright. The fastness to lime and light of the pigment produced varies with the source of the earth. As the coarseness of the usual product restrains use for paper staining, it would be worth while trying the fines mentioned for these and other applications.

A matter of more general interest is the specific difference the action of methylene blue and the basic triphenyl methane dyes. The pigment with brilliant green is turned a dirty brown permanently by vacuum drying, dried by hot air the color is soluble in alcohol; the methylene blue pigment regains its blue after vacuum drying, the color is insoluble in alcohol. This insolubility in alcohol may be connected with the ring structure, as it is exhibited to a lesser degree by acridine yellow.

Manchester, England. E. F. MORRIS.

Civil Sentiment Toward Chemical Warfare

To the Editor of Chemical & Metallurgical Engineering

SIR:—Evidence is accumulating that civil sentiment in the country with regard to chemical warfare is growing more favorable to the retention of the Chemical Warfare Service as a unit of the army and toward continued research in gas warfare. The accompanying editorial, published in a recent issue of the Chicago *Tribune*, expresses civil opinion more strongly than I have yet heard it in private conversation or seen it in the public print, outside of your own magazine.

Chemical Warfare

One of the Washington agreements outlawed gas and chemical warfare. The United States has ratified it and other agreements. The other nations have not ratified and the American War Department reports that many of the others, including Great Britain, are pressing active investigations of gas weapons.

Great Britain was in favor of prohibition. The British have two fears. One is fear of the use of gas against London and other centers of congestion and production on the island. The other is fear of the submarine against British commerce. Both the gas and the submarine prohibitions worked into the Washington agreements are believed to represent Great Britain's price for agreeing to American proposals.

American civilian sentiment opposes both gas and submarines, and opinion is not based upon reason or prospects, but upon innate abhorrence of war, particularly when it strikes the imagination as cruel and unusual. The *Tribune* believes that the prohibitions which this sentiment indorsed were unwise and detrimental to the United States.

The activity of the other nations, including the British, indicates that in no other country will there be any letup in research and preparedness in chemical warfare. Americans probably will know as little as possible about it, but the others, even promising not to use gas, will be experts in the offensive and defensive of chemical war.

That is our loss and may be our danger. Warfare which depends upon the industries, the laboratories and the science of a nation may be the protection of peaceable, industrial people. It is part of the supremacy of a high civilization over a low civilization.

All explosive shells release lethal gasses. Men in dugouts are killed by fumes, although not reached by the explosive force. Evasions of the stipulated prohibition are easy and it is a reasonable probability if not a certainty that a nation which could save itself by the use of gas would not hesitate to use it.

When men in peace and security attempt to bind men in peril and desperation they frequently fail. War is the business of overcoming an enemy's resistance and the accomplishment of a purpose by force. It is not a game. It is not undertaken in the spirit of sport. People who are fortunate do not have to undertake it at all.

When they do they will not say that they will not use a weapon with which, if they used it, they might save themselves. If a British commander, attacked by thousands of dervishes, could save his command and disperse the enemy by use of a lethal gas, he would be inhuman if he did not do so.

The sentiment against gas reveals one of the taboos of the sentimental mind and does not proceed from its reasoning.

Congress will be well advised to continue the Chemical Warfare Service and to provide adequate appropriation for research. C. W.

New York City.

An Outline of the Uses of Lime

To the Editor of Chemical & Metallurgical Engineering

Sir:—Referring to Mr. Holmes' reply[1] to my criticism of his article,[2] I cannot see the connection between his second statement and the original.

The original read: "There are three kinds of stucco—viz., straight lime and gaged stucco and sorrel (*sic!*) cement. In the first two, lime serves as a bonding agent, plasticizing agent, toughening agent and water-tightening agent. In sorrel cement the action of lime is primarily chemical instead of physical."

The reply states: "The use for lime that we had in mind for the manufacture of sorrel cement was not the addition of lime to the cement, but the use of a dolomitic lime as the base for the cement. . . . The process . . . consists of burning dolomitic lime at a temperature at which the calcium carbonate is not decomposed."

Leaving out an apparent confusion of the terms "lime" and "limestone" in Mr. Holmes' communication, I am unable to see, if the calcium carbonate is not decomposed and hence is inert, how its action can be primarily chemical. Moreover, if the calcium carbonate is not decomposed, this is not a "use of lime"; the calcium carbonate is a mere inert filler, equivalent to sand. It is a use of dolomitic limestone for the magnesia content.

On the other hand, if the original paper is correct in stating the action is primarily chemical, how is this gained by leaving the calcium carbonate undecomposed? DONALD M. LIDDELL.

New York.

Magnesite in 1921

Reports received by the United States Geological Survey, Department of the Interior, from producers of magnesite show that the quantity of crude magnesite sold or treated during the calendar year 1921 was 47,904 short tons, valued at the mines at $510,177. This quantity was less than half that for the year 1920, and smaller than that for any year since 1916. California was the only producing State, and nearly all the product was calcined for use as plastic material. The output of domestic magnesite for use in refractory products was very small.

An Informational Service For a Chemical Manufacturing Concern

By D. B. Keyes
U. S. Industrial Alcohol Co.

How a Special Department Devoted Exclusively to the Accumulation of Technical, Economic and Legal Information Can Serve the Executive, Research and Other Departments Within a Manufacturing Organization in the Chemical Industry—Details of Organization, Operation and Cost

THE growth of the chemical industry in the United States for many years was slow and faltering. It was not until the outbreak of the war that the rapid expansion of this industry required the compilation and accumulation of technical information on an unprecedented scale, as concerns both the vast amount of data to be collected and the rate at which its compilation had to proceed. In many of the larger chemical firms whole departments were devoted exclusively to informational service, and the work was carried out systematically and efficiently in order that no time might be lost in bringing the new American industry up to the standard set by its older foreign rivals.

In the present discussion the writer wishes to bring attention in a practical way to those vital points involved in the organization and maintenance of such an informational department which would be of most interest to the executive head of a chemical manufacturing concern. First, then, let us consider the nature of the demand the informational service must supply.

Who Asks Questions, and What Do They Want to Know?

Nine hundred and ninety-nine men out of a thousand would prefer to ask a question than to reason it out for themselves, or to look it up. If an information department acquires the reputation of answering quickly and correctly all questions asked of it, it will be besieged by every person connected with the company, from the fastidious office boy who wishes to remove egg from his necktie, to the member of the board of directors who would like to know the technical soundness of a new process in which he wishes to invest.

A brief outline is given below of some of the important departments in a chemical concern and the sort of information that each is most likely to desire.

The Research Department:
- Properties of substances:
  - Physical.
  - Chemical.
  - Physiological.
- Processes:
  - Laboratory preparations.
  - Manufacturing processes.
  - Recovery processes.
- Analytical methods:
  - Qualitative.
  - Quantitative.
- Specifications for products.
- Uses of products:
  - Kind of use.
  - Extent of use.
  - Details of consuming processes.
  - Laws governing use.
- Economic data:
  - Prices.
  - Consumption statistics.
  - Production statistics.
  - Imports and exports.
- Recommendations concerning past and future research.
- Recommendations received from customers concerning development of new products.

The Sales and Advertising Departments:
- Properties of products.
- Specifications for products.
- Methods of analysis of products.
- Uses of products.
- General market conditions.
- Technical sales articles.
- Technical talking points for products.
- Characteristics of competing products.
- Recommendations concerning minor difficulties experienced by consumers.

The Patent Department:
- Literature searches.
- Technical aid in drawing up applications.
- Technical aid during any patent litigation.
- Collecting evidence regarding inventorship.
- Collecting data needed in case of interference or infringement.

The General Legal Department:
- Technical aid in damage suits.
- Expert technical witnesses.

The Auditing Department:
- Cost estimates when special knowledge is necessary.

The Traffic Department:
- Properties of products:
  - Physical.
  - Corrosive.
  - Explosive.
  - Physiological.
  - Flammability.
- Kind of shipping container for special products.
- Traffic regulations concerning products and materials.

The Purchasing Department:
- Properties of substances purchased.
- Specifications of substances purchased.
- Sources for—
  - Raw materials.
  - Supplies.
  - Equipment.
- Price fluctuations:
  - Past.
  - Future.
- General market conditions.

The Plant Executives:
- Process efficiencies.
- General market conditions.

The Company Executives:
- Control of outside consulting men hired by the company.
- Summaries and criticism of work done by the research department.
- Detailed information regarding issued patents and patent applications owned by the company.
- Recommendations regarding future research and development work.
- Recommendations regarding processes offered to the company by outsiders.
- Recommendations regarding new sales fields for products.

How This Information Can Be Obtained

A great many articles have been written in recent years on the subject of making literature searches. These have been written by competent men, but usually from widely different viewpoints. Probably the best scheme for a particular purpose is the one that is worked out by the searcher himself. The characteristics most desired in the searcher therefore are ability to solve and tenacity to stick with the puzzling technical problems.

REF. Zeit. Elektrochem. 27, 563-7 (1921) AUTHOR Müller Erich

ABS. Chem. Abs. 16, 1078 (1922) TITLE Dehydroxidation of Alcohols

A large number of alcohols when dissolved in concd. alkali evolve H or hydrocarbons during electrochem oxidation. This behavior, which is similar to that due to the catalytic action of Rh, is explained on the assumption that in the oxidation of alcohol to aldehyde a metastable alcohol is formed as an intermediate product, which either alone, or in the presence of a catalyzing metal, decomps. with evolution H.

FIGS. 1 AND 2—TYPICAL AUTHOR CARDS FROM THE INFORMATION DEPARTMENT FILES

It would, perhaps, be futile to outline a definite system for searching the technical literature. Sooner or later even the most brilliantly conceived systems are bound to fail. However, a few general observations may be of interest in this connection.

The number of periodicals to be looked over regularly may be quite variable. Certainly the abstract journals such as the American *Chemical Abstracts*, the abstract sections of the *Journal of the Chemical Society* (London) and the *Journal of the Society of Chemical Industry* and the *Zentralblatt* must be consulted. The leading American chemical publications, including both technical and trade papers, as well as all publications applying directly to the particular field in which the company is operating, must be considered as necessary adjuncts. The U. S. *Official Patent Gazette* is always found valuable and interesting.

In the particular informational department on which this discussion is based, a number of good reference books were obtained, but it was not found desirable to purchase any book that was to be used but rarely and could be consulted at some convenient library.

The information department was thoroughly acquainted with every library in the vicinity and knew approximately what books and periodicals each contained. These libraries were consulted not only for special literature searches but also for interesting current, foreign and domestic publications, whenever these publications were not available at the offices of the department.

Societies which were related to the particular industry often held conventions at which technical problems were discussed and suggestions made or facts stated that would be of value to the company. These conventions were usually attended by at least one member of the information department.

No sources of information should be overlooked or forgotten. On the other hand, the list of sources should be constantly increased and the potential value of each recognized and appreciated. In other words, the scope of the information service must be constantly expanding in order to serve its needs most efficiently.

How Information Should Be Filed

There is vast difference between storing information and filing information. Treasures buried in an unknown spot may be quite safe, but treasures locked in a safe deposit box have many very practical advantages.

It is no easy task to file technical information efficiently. Evidence of this can be seen in any large library. Very little has been done in cataloging except by authors and titles. Perfection cannot be obtained in a subject file, except at an excessive cost. A workable system can be made, however, by holding to a simple outline, such as one which has been evolved after years of development.

The first principle to be adhered to by the informational department was to have an abstract of *all* information on a card that was filed by authors. These cards are more important than any of the others and therefore were the largest in size. Logically they were filed by authors, because each article or piece of information had one distinctive author while at the same time it might have covered many important subjects. No large technical file, classified by subjects, was ever found to be entirely practical.

Several small subject cards were made for each author card; these subject cards were filed separately and used only to locate the author card when the author was unknown.

The Author Card

The author cards were of two kinds, those that cover patents and those that cover articles. These cards were not kept in one file, but were divided up into separate files, each covering some field important to the company. The simplest classification was according to products, but other important subjects could be entered such as chemical apparatus, solvents, engineering materials, etc., depending entirely on the particular industry. It was found best to make the product classifications as general as possible—for example, group references to acids, bases, alcohols, aldehydes, esters and ketones. In the case of some other industry such as the dye industry still other broad classifications may be used.

The details of the author card are best seen by studying the examples given in Figs. 1 and 2. It will be noticed that a file letter and number appear at the top of the card. The letter refers to the particular file in which the author card was placed, and the number refers to the card's position among the other cards by the same author. These cross-references on the ordinary author cards referring to articles, and on the author cards covering patents, have been found to be sufficient for all practical purposes. The file letter and author number were easily put on with a rubber stamp; the remainder of the items, including the abstract, were generally typewritten. If for any reason the front and back of a card were not sufficient for the abstract, a double card was used which folds once, giving the same over-all dimensions. An excellent method sometimes used to save time in making these cards was to paste on the clipping itself. This was especially true in the case of making cards of abstracts appearing in abstract journals. The cost of extra magazine sub-

scriptions was small compared with cost of the stenographic work.

The Subject Card

The subject cards, illustrated in Fig. 3, are much smaller than the author cards and served only as a subject index for the author cards. It was quite possible for one subject card to refer to more than one author card and therefore have more than one set of file letters and numbers.

The making of useful subject cards is an art and not a science. It was found desirable to have one person make all of the subject cards, because any radical change in the system was fatal to the usefulness of the file. A common-sense basis was decided upon at the start and strictly adhered to thereafter. This system is outlined below:

The wording of the subject appearing on the subject card was divided into four groups. *First* was the "Classification Group," which gave the general class under which the subject belongs; usually there was a separate author-card file for the particular classification group. *Second* was the "Title Group," which gave the name of the individual substance, product or chemical, apparatus, etc., to which the information referred. *Third* was the "General Modification Group," which included statements such as "Manufacture of," or "Chemical Properties of," or "Use of." *Fourth* was the "Special Modification Group," which included all other subdivisions or modifications of the subject. This group naturally had a very wide range—for example, "from molasses," "vapor pressures," etc.

Some of the subjects on the subject cards would have appeared, if divided into groups, something like the following:

1	2	3	4
Esters	Ethyl Acetate	Physical Properties of ___	
		Boiling Point	
Acid	Formic	Preparation of ___	from Carbon Dioxide
Apparatus	Filter	Use of ___	to Clarify Cane Juice

The dash after group 3 was used to denote the direct relation of this group to the preceding one.

The "Classification Group" has already been said to have included all the headings that appeared as subjects of the separate author card files, and this group might also have contained other subjects that were not extensive enough at the moment to warrant a separate author card file. Examples of these subjects were: Acids, bases, esters, aldehydes, ketones, apparatus, engineering materials, etc.

The "Title Group" referred to the particular substance or thing; examples were: Formaldehyde, filter, acetone, amyl acetate, ethyl chloride, drier, etc.

When there were modifying words they were placed immediately after the class name—e.g., acetic *anhydride*, pumps *centrifugal*, etc. Although this group was necessarily very large, it was added to at will, but care was taken to prevent using more than one name for the same substance. When there was a choice between two or more names for a substance, the one that was standard in other chemical indexes was selected.

When a subject card was made, care was taken to look over both the title and the subject matter of the author card. Very often an author card was of importance to the company only because it contained information concerning one of the company's products and the name of this product did not appear in the title on the author card.

The "General Modification Group" classified the information that was given on the author card concerning the substance or thing mentioned in group 2.

FORM 40—10M-11-21

SUBJECT Alcohols, Ethyl Alcohol, Chemical

Properties of ---------; Dehydroxidation

AUTHOR Müller, Erich **A 4**

DATE 1921

FIG. 3—A SAMPLE SUBJECT CARD, WHICH IS AN INDEX FOR THE AUTHOR CARDS

This classification is best understood by looking over the following list of common subjects that appear in this group.

Physical Properties.	Properties that can be expressed by some numerical value.
Chemical Properties.	All types of reactions.
Preparation.	Laboratory methods but not commercial methods.
Manufacture.	Commercial and patented processes.
Use.	Any use that would be of commercial value.
Physiological Properties.	Data on toxicity. Any biological reaction.
Economic Data.	All data on trade and production, quantities and values.
Determination.	Quantitative.
Detection.	Qualitative.
Analysis. Occurrence. Recovery.	For impurities.
Purification.	Freeing from impurities.
Separation.	From other substances.
Concentration. Constituents.	Components of a mixture or a solution.
Specifications.	Requirements for various grades or mixtures.

The list of subjects was added to whenever it was deemed expedient, but it was thought best to keep this list as small as possible. In case the subject of this group 3 referred to the general class mentioned in the corresponding group 1, then group 2 was omitted. An illustration is:

1	3	4
Acids	Physical Properties of	Dissociation

The "Special Modification Group" represented a modification of the subject given in group 3. Not much attention was paid to this group, except to see that it was present and that it was short and "meaty." Ex-

amples of complete subjects containing this group, are given below:

Esters, Amyl Acetate, Use of ——,
as a solvent for pyroxylin
4

Aldehydes, formaldehyde, Preparation of ——
from carbon monoxide
4

As this was the last group and the one which covered the widest field of subjects, it was not considered necessary to make any particular classification.

Subject cards were filed alphabetically in the ordinary manner, but as many subdivision cards as possible were used to facilitate the filing and locating of a particular subject.

Both author card and subject card files were kept in duplicate—one complete file at the research laboratory and one in the information department. In the research laboratory the subject cards were always kept in the file in case any author card that may have been taken out and lost could be located in the information department's file and duplicated. Fire insurance was carried on these cards, the amount covering the cost of the copying.

Other Files and Forms

All photostats and manuscripts such as translations, copies of odd journals, etc., were filed by author and had corresponding author and subject cards filed in their respective files. The author cards stated where the manuscript could be found. This manuscript file also contained all reports and any memoranda that were not made by the research staff.

Research or laboratory reports were filed separately and had a separate author- and subject-card system. These reports were also filed by author or by some very simple subject classification. The author card stated where the report might be found.

A patent specification file for all patents not owned by the company was arranged according to author. These, too, had corresponding author and subject cards in the main file. The author card stated where the specification might be found. The specifications of patents assigned to the company were conveniently kept in a note book form, one book for U. S. patents arranged alphabetically by countries. Data on applications filed in the United States by members of the company were kept in a loose-leaf notebook. The following information was included: Name of inventor, title, serial number, date of filing, abstract of subject matter; and later when the patents were issued, the numbers and dates of issue were added. Copies of applications and all legal papers connected with the cases were kept in folders and filed alphabetically by inventors. These folders did not need any corresponding author and subject cards.

Special forms were made up to cover all material required by the patent lawyers in order to make up an application. These forms were filled out by everyone connected with the invention. After the application was filed a special form of an affidavit was filled out by the inventor. This affidavit gave the data necessary in case of an infringement or an interference. Both of these papers were filed in the folders mentioned above.

The manuscript, report and patent specification files were kept in duplicate, one copy in the research department and one in the information department. It was found convenient in certain cases to have a third or fourth copy in other departments.

The Organization

An adequate organization for the average large chemical manufacturing concern would consist of a chief, two technical assistants and three stenographers.

The chief may be a consulting chemist or chemical engineer, who devotes only a part of his time to the information department, the rest of his time being used for consulting work on problems arising within the company. This man must be thoroughly familiar with all of the company's problems and he should be able to foresee the difficulties, both technical and economic, that may arise in their consideration. In brief, he should be a capable chemist, engineer and business man.

The two assistants should be well-trained technical men, who are able to look at a problem from the economic viewpoint. Long experience is not essential. One should be well qualified to read technical French, German, Italian and Spanish. One should handle the routine work, but should be able to prepare an intelligent abstract of a technical article. Both should soon acquire knowledge of the whereabouts of all available sources of information. Naturally this knowledge increases steadily with time. One of the assistants should familiarize himself with the gathering of statistics.

Even the stenographers should comprehend the fundamental principles of chemistry. They must be able to take several hours of dictation covering some technical or scientific subject. Six to eight months is usually necessary to train the average stenographer to be efficient in such a position. Quite often a stenographer desires a special form of shorthand to cover the particular technical terms that occur many times in the work. In case the laboratory is not located in the same building as the information department, it may be desirable to have one of the stenographers stationed in the laboratory library to handle the routine of that department, such as the writing and filing of reports.

The Informational Service in Operation

The current cards covering abstracts of interesting articles were sent daily to the director of the research department. Under ordinary conditions these amounted to about 200 a month and were taken from 60 to 100 publications issued during the same period. The subject cards for these author cards were filed at the laboratory and some of the author cards were sent by the director to various research men. The information department always filed their copies promptly and they were therefore immediately available to all who are interested in them.

Special cards covering more important subjects were sent to the research director marked for his special attention. Likewise photostats, reprints, special copies of periodicals and books were routed through the organization. These were always accompanied by author and subject cards for the research department's files.

Special reports and memoranda were usually sent to the person who made the request for the information and occasionally copies were sent to the general manager, the director of research or the sales manager, depending on the subject. Cards covering these reports were filed as stated previously.

There were many other special features that increased the speed and efficiency of the information service. Obviously only a few can be mentioned here.

One assistant spent most of his time in a large outside library where he could be easily reached by phone.

This library was equipped with a photostating service so that photostats of articles up to fifty pages in length could be obtained within 24 hours after the request was made.

The company's purchasing department was posted regarding all available sources for odd books and periodicals, but the actual subscriptions to periodicals were handled through the informational department.

The valuable services rendered by the office of the editor of *Chemical Abstracts* were utilized to good advantage. The Washington representative of the company's patent attorneys was called upon when photostats of foreign patent specifications were desired in a hurry.

The information department had numerous professional friends who were willing at all times to give bits of information and minor opinions in return for similar services.

The chief of the information department was in close touch with all research men employed by the company, in order to be qualified to judge the needs of the research department. Physically, it is easier to talk than it is to write or even to dictate; therefore frequent conferences with the research men were found to be unusually helpful. This was also true of conferences with the other departments.

After a large and exhaustive card file had been made up, difficulty was experienced in educating the men to make use of it. It happened on several occasions, however, that the basic principles and patentable ideas of some "invention" were found fully described on an information card. After this occurred, the "inventor" was usually more inclined to make use of the information file before starting work on his next idea.

The Cost of the Informational Service

A statement of the average yearly cost of an information department is given below:

Salaries	
Chief (half time of a high grade consulting chemical engineer)	$4,000
Two technical assistants ($3,000 each)	6,000
Three stenographers, (average $100 per month)	3,600
Expense of trips (Depending on location of laboratory and information department)	600
Office rent (15,000 sq.ft., including libraries; $3 per sq.ft.)	4,500
Photostats	300
Periodicals	150
Books	250
Incidentals	100
Total	$19,500

It is understood, of course, that the proposed department would be for a relatively large chemical manufacturing organization. The department and its cost would be proportionately smaller for a smaller company.

New York City, N. Y.

French Chemical Industry Improving

The heavy chemical industry of France is making rapid strides of improvement, according to Commercial Attaché D. C. Huntington, who writes from Paris on June 12. He reports that business is much better than a year ago and prices are well maintained. Chemicals for tanning, glassworks and paints, however, still remain inactive. Synthetic products for drugs and perfumes are satisfactory. The important chemical firm, Etablissements Kuhlmann, reported at the annual meeting that its plants now working at 85 per cent of capacity, as compared with an average of 50 per cent for 1921. This company has successfully made two wage reductions.

Legal Notes

By Wellington Gustin

Eibel Patent for Improvement in Fourdrinier Machines Held Invalid and Not Infringed

In a long and well-considered opinion the United States Circuit Court of Appeals reversed the District Court, which had given a decree in favor of the Eibel Process Co. in its suit brought against the Minnesota & Ontario Paper Co. Suit was for infringement of the Eibel patent 845,222. The patent claims to be an "improvement in Fourdrinier machines."

The Fourdrinier has been the best known and most commonly used paper-making machine for generations. It consists, in its first section, of an endless wire sieve, passing over a series of rolls at a constant speed. At the wet or breast roll end of this running wire sieve there is discharged from a flow box through a sluice a stream of paper-making stock, consisting of wood pulp, sometimes with added mineral matter, mingled with from 135 to 200 times its weight in water. The stock has the appearance of diluted milk. The wire mesh over which the stock travels has also a sidewise shaking motion to assist in the proper fitting and interlocking of the fibers. The stock is carried along on this wire about 30 ft., draining off its water as it goes, until it reaches the couch rolls at the farther end of the wire, where it is pressed into the form of a uniformly distributed wet pulp or web strong enough to hold together. It is then carried through a series of pressing and drying rolls and calenders, which constitute the drying end of the machine. About 20 ft. from the breast roll are placed suction boxes in contact with the under surface of the wire operating by means of a partial vacuum to assist in the extraction of excess water remaining in the pulp and to compact the sheet by atmospheric pressure. This is but a meager description of the first part of a large and complicated machine upon which paper stock goes in highly diluted liquid form, is subjected to draining, shaking, meshing, pressing and heating processes, until it emerges as a smooth fabric newsprint.

No Valid Patent on Mere Principle

A Fourdrinier machine costs approximately $100,000, and for economy is run continuously day and night. Speed and quality of paper have ever been the quest of paper makers. This is what the Eibel principle claims. But the court says of course there can be no valid patent on a mere principle. Claims 7 and 8 of the Eibel patent it holds void for lack of invention. Claims 1, 2, 3 and 12, if construed to cover any elevation of the breast roll of the paper-making wire appreciably greater than that shown by the prior art, to gain speed, the court says are void for indefiniteness and as differentiated from the prior art only by a mere change in degree. If construed in accordance with the natural import of the language, as requiring such a pitch of the paper-making wire as will alone, through gravity, without regard to the head in the flow box, bring about speed equality between the stock and the wire, and practically eliminate the drag of the wire, it discloses no useful invention, since no such pitch has even been used or claimed to be useful in practice.

Modern Handling Methods in the Manufacture of Electrical Porcelain

Electrical Porcelain Plant of the Square D Co. — Experience Obtained in Metal Working Applied to the Manufacture of Porcelain — Economies Realized Through the New Methods

By Graham L. Montgomery

THE Square D Co. manufactures electrical safety devices, such as switches, panel boxes, and so on. A large amount of porcelain enters into these devices for purposes of insulation. Originally all this porcelain was purchased from outside manufacturers. This had the advantage of relieving the Square D Co. of the burden and responsibility of running a porcelain plant. On the other hand, it was attended with many disadvantages, such as inadequate supply, delay in deliveries and high costs.

In consequence, shortly after the armistice, the Square D Co. purchased the plant of the Peru Electrical Porcelain Co., in Peru, Ind. This was rather an old plant and perhaps not in the best of condition. But it was fully capable of turning out high-class product. The methods used there were those still generally used in similar plants and did not include any of the more recently developed equipment, such as tunnel kilns and continuous driers.

Application of Methods From Metal-Working

After the purchase of this plant a study was made of the equipment available for porcelain manufacture and of the methods generally used in such manufacture. It was found that the new plant was well up to the standard and the only improvements in methods that could be made would be by using the tunnel kilns or other equipment mentioned above. This equipment is expensive and the plant as then existing did not warrant such an expenditure.

The new owners were men experienced in the methods used in metal-working plants. It was immediately evident to them from their study of porcelain manufacture that there were possibilities of effecting economy and increased output if the methods of material handling with which they were familiar were applied to their new venture. Nothing was discovered along this line in other porcelain plants except in some few cases where conveyors were used for handling the raw clay as it was unloaded from cars.

Where Handling Equipment Was Used

Bringing their past experience of handling methods to bear in a study of the existing routine of manufacture at Peru, the works engineering department from the main plant in Detroit discovered many opportunities for economy and increased output. From the filter presses onward to the shipping room a complete handling system was devised which was inexpensive to install and which necessitated but little change in the existing manufacturing equipment.

For unloading the raw clay from the cars and for handling to and away from the blungers, methods were used which were in the main the same as are in use in many other plants. The handling used throughout the rest of the manufacturing process naturally falls into four main divisions. These are: First, handling the filter press cakes into and out of the drier and to the crusher. Second, handling the clay through crusher, tempering bed, dust mill and screen. Third, handling

KILN BUILDING, SQUARE D CO., PORCELAIN PLANT, PERU, IND.

the dust to the press room and the unfired products of the presses into and out of the drier and to the saggers. Fourth, handling saggers to the kilns, out of the kilns, and to the packing room.

Types of Handling Equipment Used

The types of handling equipment which were found to be best adapted for use in porcelain manufacture were the hand lift truck, the belt conveyor and the gravity conveyor.

The hand lift trucks are used for handling filter cakes, for handling steel cars of dust, for handling the unfired product of the presses into and out of storage. The skids used for these lift trucks are of two types. Those for handling and storing bulky materials are with removable containers which may be locked to the skid and which can be built up to any desired height. Those for handling the product of the presses and the filters have racks attached. These racks consist of two uprights, fastened along the longitudinal center line of the skid with twelve horizontal supports of ¾-in. pipe on each side.

This total equipment consists of eight lift trucks and about 600 skids and racks. The method in which these trucks and the belt and gravity conveyors are used is described below.

Handling Cakes From the Filter Presses

By the usual method, the cakes from the filter press are carried into the drying room by hand, placed on horizontal stationary shelves, and when the drying is completed, carried out again and to the crusher. The new way utilizes the skids, which are provided with racks. With twelve supports on each side of these racks, twenty-four removable shelves or boards can be laid on each rack. The filter cakes are laid on these boards as they come from the press.

As soon as the shelves of a rack are completely filled, that skid is picked up on a lift truck and conveyed into the drier. When the drying is completed, the lift truck takes the skid to the crusher, beside which it is allowed to rest. As the workman operating the crusher desires to feed it, he takes one of the removable boards from the rack and dumps its load of dried filter cakes into the hopper of the crusher. The empty board is replaced on the rack and when the whole load is emptied thus into the crusher the empty rack is replaced by the lift truck in position near the filter press.

From Crusher to Dust Mill

The product of the crusher discharges into the inclined belt conveyor shown in the accompanying photograph. This conveyor consists of a simple belt running in a wooden trough and inclined about 45 degrees. Slats are secured to this belt at close intervals to aid in carrying the crushed clay up the incline. At the top of its run this belt discharges into a swinging metal spout, by means of which the clay can be placed in any one of the several tempering bins as desired.

From the tempering bins the clay is shoveled onto the horizontal flat-belt conveyor which feeds the dust mill. This conveyor, also shown in the photograph, runs in a wooden trough and is provided near its discharge with a toothed wheel which serves to break up any lumps and thus prevent clogging of the dust mill.

In the dust mill the clay is ground to a fine powder. Referring again to the illustration mentioned above, a wooden housing will be seen at the left. This contains the revolving screen, so placed that the steel cans used to hold the screened dust can be wheeled under it by the lift trucks and left standing there. The photograph shows a wooden chute leading from the dust mill into the wooden housing. The centrifugal force developed in the mill throws the dust through this chute into the screen. The screen is tilted, with its lower end at the point where the dust enters. The driest dust, being lightest, is thrown to the high end. In this manner the dust is separated into four general grades corresponding to the four meshes of the screen and roughly in accordance with the degree of moistness. As the screen revolves these grades sift through its meshes into cans waiting below. The rejects roll back and out of the screen at its low end to be put back through the process or discarded, as the case may be.

When a can is filled it is taken by a lift truck to the elevator. The elevator takes the can—on its skid—to the second floor, where the press room is located. Here another lift truck picks it up and places it conveniently for the worker at one of the presses, it being removed at the same time from the skid, which is taken back for another load.

A Special Type of Hand Truck for Dust Cans

Recently a new method of handling the dust cans has been developed. The cans were provided with trunnions, placed near the tops so that they could be easily swung. Two special hand lift trucks were provided, one for each floor, built to engage these trunnions, lift the cans clear of the floor, and then transport them to the desired point. This is an improvement over the skid method, as the can had to be lifted by hand on and off of the skids, which took some little time and labor—now eliminated.

Handling From the Presses Through the Driers to the Sagger Loading Dock

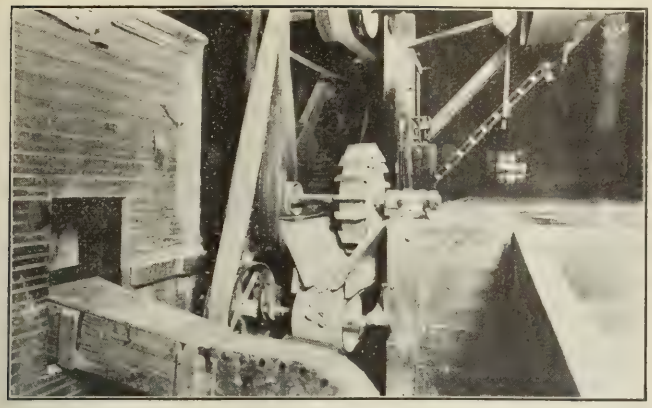
As the unfired pieces leave the presses the press operator places them on a tray which rests on the table at the left side of his machine. Reference to the accompanying photograph will show the arrangement of dust cans, presses, trays and rack skids. The trays are made to fit on the horizontal supports of the rack skids as described in a preceding section. When a rack is filled with loaded trays it is taken by lift truck into the drying room, remaining there until sufficiently dry to be safely fired.

When the drying is completed, the lift truck is again pressed into service and the rack of dried pieces is taken to the room where the cleaning and glazing is done. After this is completed the lift truck again picks up the skid and places it on the elevator. It is thus conveyed to the sagger loading dock on the first floor adjacent to the kilns.

In the illustration which shows the press room, it will be noted that some of the racks are on wheeled platforms. This method of handling was formerly used but the lift truck method has proved to be quicker cheaper and more flexible.

Handling System for Saggers

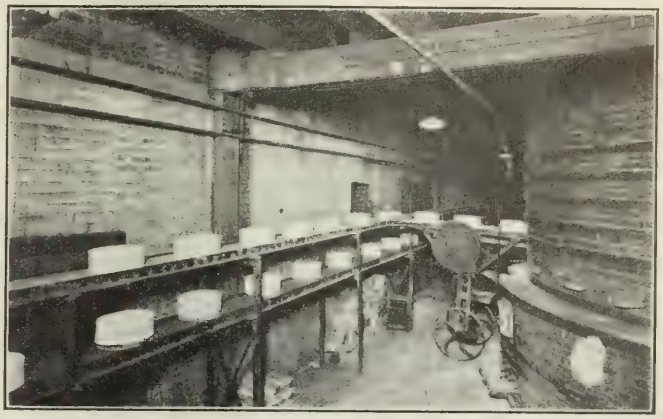
Due to the large variety of shapes and sizes comprised in the product of the plant, there are twelve different types of saggers in use. For this reason it is necessary to have a large number in storage. The size of the storage thus needed has made it necessary for the saggers to be stored some distance away from this sagger loading department.



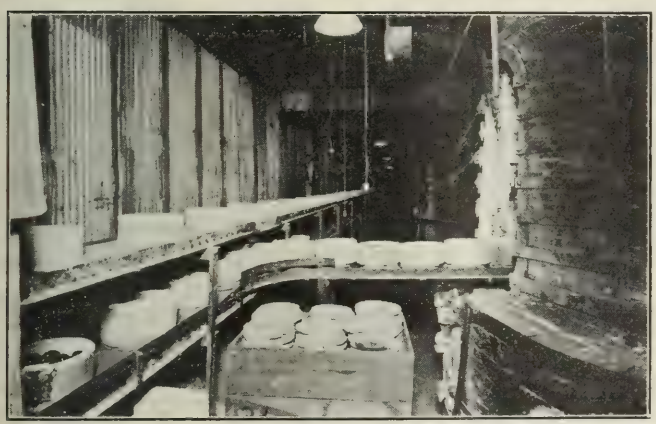
CLAY CONVEYORS, DUST MILL AND SCREEN HOUSE

PRESS ROOM

SAGGER LOADING DOCK



LOADING SAGGERS INTO KILNS BY CONVEYOR



CONVEYOR UNLOADING KILN AFTER FIRING

INSPECTING, CHECKING AND PACKING DEPARTMENT

A plain, flat skid is taken into the sagger storage and the saggers desired are placed on this and taken to the sagger loading dock, where they are placed conveniently for the workers whose duty it is to pack the unfired ware in them. After the firing is completed, the sagger filled with ware is moved to the packing department and the ware taken out. The empty saggers are placed on a flat skid and taken by lift truck back to the sagger storage, where they are unloaded and stacked by hand until again needed.

Loading the Saggers

In the illustration which shows the sagger loading dock will be seen several of the loading benches. These benches are provided with shelves at the top on which are placed trays of the unfired ware. A skid rack of these trays placed close to the bench and a skid loaded with the appropriate style of sagger is placed at the end of the bench. The worker then packs the ware into the saggers, stacking the filled saggers close to the conveyor which leads to the kilns.

The most important part of the conveying system is that part which loads and unloads the kilns. The success of its operation depends entirely upon the manner in which the ware is packed in the saggers. Each piece must be so placed that it cannot knock against the next piece or the sides or bottom of the sagger; and it must be braced in position so that it will keep its place.

The conveyor used for kiln loading is also used for unloading, the top strand carrying ware to the kilns and the bottom strand carrying it away. This conveyor is made up of a two-decked roller conveyor with 16-in. rolls spaced 4 in. apart on the upper deck and 8 in. apart on the lower deck. Running over this roll is a flat canvas belt of heavy construction—14 in. wide.

This use of closely spaced rollers and a flat belt provides a bed on which the loaded saggers ride smoothly and evenly when the belt moves slowly, at about 25 to 30 ft. per minute.

The conveyor is 180 ft. from center to center of pulleys and passes directly by and about 8 ft. away from the loading and unloading doors of the six kilns. At the loading dock, the worker places a wooden pallet on the belt and on this pallet places a loaded sagger. This is repeated rapidly enough so that the spaces between the saggers are about 4 ft., care being taken that these spaces shall not be less. At the speed which this conveyor travels, this gives a delivery of loaded saggers to the kiln equaling about 400 per hour.

How the Saggers Are Conveyed Into the Kilns

The chief difficulty encountered in laying out this system was to devise a workable means for automatically taking the loaded saggers from the main belt onto an auxiliary belt traveling at right angles and taking the saggers into the kiln. It is necessary to make this transfer in such a way that the sagger is not disturbed sufficiently to tip or break the unfired ware.

The method adopted to accomplish the transfer is ingenious but simple. Directly opposite the door of each kiln is a section of the roll conveyor bed of the main belt which is removable. A portable belt conveyor is used as the connecting link between the main belt and the kiln. On the end of this which is toward the main belt two ball-bearing rollers are mounted beneath the frame with their axes of rotation parallel to the line of travel of the portable belt. These rollers are exactly similar to those forming the bed for the main belt.

The removable part of the main belt bed—which corresponds in length to the width of the portable belt frame—is removed. The end of the portable belt carrying the two rollers is then pressed down into this opening and bolted in place. The two rollers serve to guide the main belt around and below the portable belt. When this is completed, the portable belt is running at a level slightly below the general level of the main belt and at right angles. Its other end extends into the kiln—where it delivers onto a short section of roller conveyor which serves as a collecting place for saggers until the kiln-loading crew can dispose of them.

At the corner between the two belts a snub wheel will be noticed. When a sagger comes along the main belt it travels out over the portable belt until it tips through its own weight. The motion of the portable belt pulls it over until it comes against the snub wheel. This serves as a guide and it travels smoothly around the corner and into the kiln.

Unloading the Kilns

For unloading the kilns, a portable gravity conveyor is used. This extends from inside the kiln to the return or bottom strand of the main belt conveyor. The portion next to the main belt curves through 90 degrees and thus delivers in the same direction as the main belt travels. This will be seen in the accompanying photograph.

The method of attaching the portable gravity to the main belt is very ingenious. The last roller is removable. This is removed and slipped under the belt, and then put back and bolted in place with the belt over it. When the frame of the gravity is bolted to the main belt this serves to press the belt against the under side of the second roller on the gravity and revolves it in a reverse direction. As a consequence, the loaded saggers, as the pallets which they travel on hit this roll, are slowed up and come easily onto the main belt.

After passing this point, the loaded saggers travel on the main belt to a point just short of the sagger loading dock. Here the belt makes a vertical dip and the saggers slide off onto a gravity roller conveyor which extends through the inspection, sorting and packing room.

Inspecting and Packing

As the saggers pass along on this gravity conveyor the inspectors sort them and throw out the damaged pieces. The proportion of waste is carefully counted. The saggers then pass on to the packing department, in which location the conveyor is horizontal and they slow up enough for the packers to remove the good ware and pack it. The accompanying photograph clearly shows how this department is arranged. Pallets, saggers and cartons of finished ware are all taken on skids and lift trucks to their various destinations.

This system has accomplished three advantages as follows: 1. It has reduced the manufacturing cost for the product. 2. It has reduced the labor force necessary. 3. It has materially increased the output. All the above has been achieved with an expenditure of less than $10,000 on handling equipment.

Some Economies Realized

Formerly in loading a kiln ten men were required for 20 hours—a total of 200 man-hours. With the conveyors two men are required in the kiln and three men to load saggers at the dock for a total of 7 to 8 hours, or 40 man-hours. This is a clear saving of 80 per cent in this, the most costly labor operation in the plant.

Formerly in unloading a kiln the saggers were carried out by hand, their contents dumped into a tote box and then this carried to the inspecting and packing department. This method took five men working 20 hours, or 100 man-hours. The new method takes six men 8 hours, or 48 man-hours. This is a clear saving of 50 per cent of the labor cost on this operation. In addition, far more breakage occurred in the old method of handling than now occurs throughout the process.

The management stated to the writer that through the use of the conveyor which loads and unloads the kilns a net saving in labor and burden amounting to $125 per day is realized. As the interest charges on the total handling system are not over $50 per month and the operating, maintenance and depreciation charges are very low, the saving effected is really amazing.

A study of the savings resulting from the use of the skids and racks with the lift trucks has not as yet been made; but it is evident to the management that they obtained many advantages through this equipment. One of the outstanding advantages realized is a reduction—in the proportion of 1 to 20—in the time a man has to be in the hot atmosphere of the drying rooms and also in the time which the drying room doors have to be open with consequent loss of heat.

The writer wishes to acknowledge his debt to the management of the Square D Co. both in Peru and in Detroit and to the Dow Co., of Louisville, Ky., which made most of the conveyors described, for their kindness in making available the data of this article.

Heat Losses From Bare and Covered Wrought-Iron Pipe*

At Temperatures up to 800 Deg. F.

By R. H. Heilman†

MANUFACTURERS of pipe coverings often are required to guarantee that the application of a specified heat-insulating covering will effect a certain percentage saving of the heat which would be lost entirely from a bare pipe. Since the bare-pipe loss is the 100 per cent value against which the losses from the covered pipe must be compared, it is essential that the loss from the bare pipe shall be known accurately.

Many investigators have studied the heat losses from bare pipes. Perhaps the most noteworthy of those experimentalists was the French physicist Péclet. Owing, however, to the fact that Péclet's experiments were conducted at very low temperatures, while subsequent investigators confined themselves mostly to one pipe size only, the Mellon Institute deemed it advisable to carry on the research to much higher temperatures and on 1-in., 3-in. and 10-in. pipe.

The 1-in. pipe was selected for test at the higher temperatures, as the relatively small amount of heat loss from a 1-in. pipe could not greatly affect the room temperature. This pipe was run up to a temperature of 800 deg. F. The average room temperature throughout this test was 81 deg. F., and the temperature did not vary more than 1.8 deg. F. during its progress.

The locations of the curves for the 3-in. and the 10-in. pipes were obtained by experiment at the lower temperatures, as indicated by the solid lines in Fig. 1. The values for the higher temperatures are the result of extending the curves parallel to the curve obtained for the 1-in. pipe. This procedure was necessary because of the fact that the larger pipes could not be raised to the higher temperatures without raising considerably the temperature of the room.

In Table I the loss in dollars and cents and in pounds of coal per 100 lineal feet of horizontal bare iron is tabulated for temperature up to 664 deg. F. The loss varies from $1.32 for 100 lineal feet of ½-in. pipe at 180 deg. F. to $297.50 for 100 lineal feet of 18-in. pipe at 664 deg. F.

In order to calculate the loss of heat from an insulated pipe or boiler, it is necessary to know the total temperature drop from the pipe to the surrounding air; and to enable one to make accurate calculations, it is required that the component temperature drops be known.

The total temperature drop from the steam inside a pipe to the outer air can be considered as made up of:

a. Drop from steam to the outer surface of the pipe.
b. Drop from outside surface of the pipe to inside surface of the insulation.
c. Drop from the inside surface of the insulation to the outside surface of the insulation.
d. Drop from outside surface of the insulation to the surrounding air.

The temperature drop from the steam to the outer surface of the pipe depends upon the resistance to heat flow offered by the film at the inner surface and the resistance offered by the iron wall of the pipe. No attempt was made to measure this temperature drop in the present investigation, as it was considered to be so small as to be negligible.

†Industrial Fellow, Mellon Institute.

[1]In this table coal has been figured at $4 per ton of 2,000 lb., 13,000 B.t.u. per lb. of coal; labor, boiler-room expense, etc., taken at $1 per ton, making total value of coal fired at $5 per ton. Boiler efficiency taken at 70 per cent; air temp., 70 deg. F. Experimental data obtained at the Mellon Institute.

The temperature drop from the outer surface of the pipe to the inner surface of the covering for 1-in., 3-in. and 10-in. pipe is shown in Fig. 2. These curves show that the temperature drop increases as the pipe diameter decreases. A test was also made on a 3-in. pipe with an air space of 1.2 in. between the surface of the pipe and the insulation. By comparing this curve with the curve for an air space of 0.1 in., it is observed that the temperature drop for a 1.2-in. air space is only a few degrees more than for an air space of 0.1 in. This is probably due to the fact that for air spaces much greater than 0.2 in. convection currents are increased, thus causing an increase in heat loss. An examination of Fig. 2 shows that the temperature drop for a 0.1-in. air space is approximately equal to that for 0.1 in. of commercial insulation, so that this temperature drop can be neglected in calculations and the pipe covering considered as fitting close to the pipe with the pipe temperature and the temperature at the outer surface of the covering as the temperatures bounding the covering.

The drop in temperature, or the temperature gradient curve through the insulation, depends upon the thickness of the covering and the curvature. In a cylindrical covering the resistance to heat flow diminishes as the outer surface is approached, the temperature drop becomes less, and the gradient curve is bowed downward if the curvature alone is taken into consideration. However, the absolute conductivity decreases as the outer surface is neared, with a consequent bowing up of the gradient curve, and the two tend to counteract each other, so that the temperature gradient curve may be bowed either up or down or be a straight line, depending upon the curvature of the cylinder. The temperature gradient curve for a flat surface should bow up.

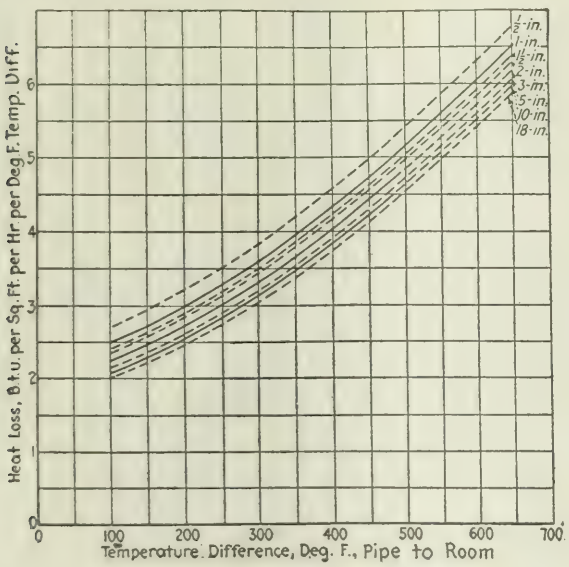

FIG. 1

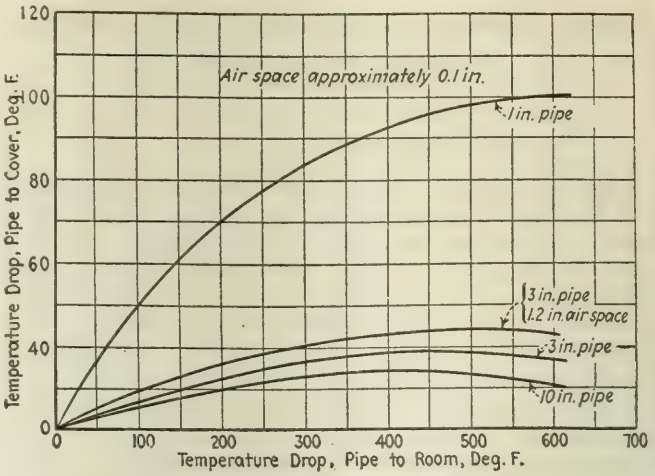
It is highly desirable that tests should be conducted on commercial steam pipe coverings of different thicknesses and at different temperatures, in order to obtain mean absolute conductivity curves for the different thicknesses.

The temperature drop from the outer surface of the insulation to the surrounding air depends upon the amount of heat emitted by radiation and air contact. This in turn is dependent upon the nature of the surface of the body, the shape of the body, the excess of its temperature over that of objects to which radiation takes place, and the absolute value of the temperature of these bodies. Commercial steam pipe coverings are invariably covered with a canvas jacket. From the above mentioned facts it is obvious that the loss from a canvas surface at a given temperature is independent of what is under the canvas, so that, if the canvas-loss law can be ascertained, this law may be applied to the loss from steam pipe coverings and thus the temperature of the outer surface of the insulation can be determined. In making calculations of heat loss through an insulation, it is absolutely necessary to know the temperatures at the inner and outer surfaces.



Air space approximately 0.1 in.
1 in. pipe
3 in. pipe
1.2 in. air space
3 in. pipe
10 in. pipe
Temperature Drop, Pipe to Cover, Deg. F.
Temperature Drop, Pipe to Room, Deg. F.

FIG. 2

Péclet made a careful study of the heat emissivity from various surfaces, canvas surfaces included. As mentioned, however, his experiments were conducted at relatively low temperature. McMillan[2] made a study of the heat emissivity from a canvas surface in his study of commercial steam pipe coverings, but confined his experiments to one pipe size only. Nevertheless, McMillan's results in the form of a curve present a readier means of calculating the losses from steam pipe coverings than do Péclet's, whose observations, while taking all the variables into consideration, are in too complicated a form to provide a ready means of calculation.

Since McMillan's canvas-surface-loss curve was obtained from experiments on one pipe size only, this curve can be used in making calculations on coverings of a diameter approximately the diameter of the cover-

[2] *Trans.*, A.S.M.E., vol. 37, p. 928.

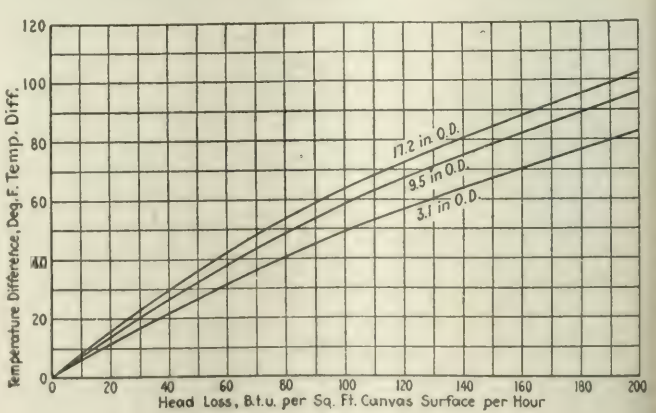


FIG. 3

ings tested. In order to be able to calculate the loss of heat from pipe coverings of any diameter, it has been necessary to obtain the canvas-surface-loss curves for various diameters. Accordingly, coverings were tested on the 1-in., 3-in. and 10-in. pipes used in determining the bare-pipe losses. The average outer diameters of the coverings used were 3.1 in., 9.5 in. and 17.2 in. The results of these tests are shown in Fig. 3.

In order to simplify the calculations necessary to determine the loss of heat through coverings of various diameters, an equation for the three curves shown in Fig. 3 has been derived. In this equation

$$T_d = \frac{272.5\,h}{h + \frac{564}{D^{0.19}}} \qquad (1)$$

T_d = temperature difference between canvas surface and room, deg. F.
h = total B.t.u. loss per hour per square foot of canvas surface.
D = outer surface diameter, inches.

This equation is approximately accurate for diameters up to 2 ft.

Thermocouples were used in determining the canvas temperatures. During this investigation it was found that the couple, when just inserted under the canvas, would invariably read low. This difficulty was overcome by inserting it under the canvas for a distance of several inches, this distance depending upon the size of the couple and the temperature of the covering.

A covering 2 in. thick, having a mean absolute conductivity coefficient of 0.56, is placed on a 4½-in. outside diameter pipe maintained at a temperature of 400 deg. F. The temperature of the surrounding air is 700 deg. F. Determine the heat flow H in B.t.u. per hour per sq.ft. of pipe surface.

The heat flow through a cylinder is given by the following equation:

$$h = \frac{K(T_1 - T_2)}{r_1 \log_e \frac{r_2}{r_1}} \qquad (2)$$

where T_2 is the temperature at the outer surface of the covering. To obtain T_2, knowing only T_1, the pipe temperature, and T_3, the room temperature, it is necessary to change the form of the equation so as to include T_d, thus:

$$h = \frac{K(T_1 - T_3 - T_d)}{r_2 \log_e \frac{r_2}{r_1}} \qquad (3)$$

in which

K = mean absolute conductivity of insulation.
r_1 = radius of inner surface of insulation, inches.
r_2 = radius of outer surface of insulation, inches.
T_d = value given by equation 1.

Substituting in equation 3, there results

$$h = 0.56 \left[\frac{400 - 70 - \frac{272.5\,h}{h + \frac{564}{8.5^{0.19}}}}{4.25 \log_e \frac{4.25}{2.25}} \right]$$

$$= 0.207 \left(330 - \frac{272.5\,h}{h + 375} \right)$$

$$= \frac{-\sqrt{363.1 = 363.1^2 + 4 \times 25{,}600}}{2}$$

$$= 60.4$$

whence $H = 60.4 \times \frac{4.25}{2.25} = 114$ B.t.u. loss per sq.ft. of pipe surface.

The temperature of the outer surface of the covering can be obtained by substituting the value h in the equation $T_d = 272.5h/(h + 375)$, reducing to $T_d = 37.6$. Therefore the temperature of the outer surface of the covering is

$$37.6 + 70 = 107.6 \text{ deg. F.}$$

The utility of these equations will be apparent to anyone who has occasion to calculate heat losses.

Studies on Cast Iron

Conditions obtaining in foundry practice have been vastly improved in the last 30 years, according to Richard Moldenke, in a brief paper before the 1922 meeting of the American Society for Testing Materials. Buying pig iron by its analysis is the rule everywhere and fracture is seldom an issue. The foundry foreman of today has no difficulty in calculating his mixtures chemically, and the composition of the various types of castings are almost standardized. Melting practice has now been placed upon a scientific basis in the foundry, so that there is little excuse for heavy losses from inferior metal.

There still remains, however, a critical study of the principles and practice connected with the rational gating of molds. Furthermore, many points in the following outline need investigation, in order to collect definite data on many still obscure problems relating to foundry practice.

I. Relation between chemical composition and physical properties, such as fusibility, fluidity, set, contraction, chill, hardness, strength, specific gravity, etc.

II. Influence of variations in foundry practice upon chemical composition and physical properties, as in the following summary:

Mixture Characteristics: Pig and scrap proportions, steel additions, charcoal or coke irons, "direct" blast-furnace metal.
Metals' Characteristics: Clean or with sand, rust, "burnt" scrap, shot, borings, salamanders and heavy section pieces.
Melting Characteristics: Rational or poor charging and melting practice in cupola or furnace, normal hot iron or oxidized "lifeless" quick-setting metal. Duplexing in electric furnace for better superheat, deoxidation and desulphurization.
Temperature Characteristics: Pouring temperature and rate of cooling due to mold surface characteristics, whether green or dry sand, metal molds, use of chills, section of castings, refractory quality of mold, gating of molds.
Molecular Treatment: Annealing, seasoning, rumbling, repetition, heating and cooling.

} Effect on {
Grain structure.
Internal shrinkage, porosity.
Blowholes.
Hardness.
Strength.
Internal stress.
Carbon condition.
Changes in other contained elements.

The following bad characteristics in castings are sufficiently important to warrant special mention in separate paragraphs:

III. *Shrinkage* and *Segregation:* As specially affected by composition, oxidized metal through bad melting practice, cold metal, irrational gating methods, insufficient feeding opportunity, low ferrostatic pressure.

IV. *Blowholes:* As specially affected by oxidized ("burnt") metal in charges or through bad melting practice, cold iron, low ferrostatic pressure, wet mold surfaces, wet or insufficiently vented cores.

The Sulphuric-Acid Treatment Of Petroleum Products

Chemistry of the Process—Action of Sulphuric Acid on the Various Hydrocarbons and Other Constituents of Petroleum—Review of Factors Affecting the Successful Application of This Treatment in Petroleum Refining

By Carl J. Von Bibra
Chemical Engineer

MOST of the petroleum products derived from either the ordinary distillation or the cracking processes must be refined before being placed on the market as finished articles of commerce. This refining generally takes the form of a chemical treatment. This is not always the case, however, as other methods depending on a physical action such as filtration are also in common use. Sometimes both chemical and physical methods of refining are employed.

The refining of petroleum products naturally divides itself into two branches. One of these, the refining of light oils such as gasoline and kerosene, has until recently been considered rather a simple process. It is now becoming more complicated, however, because of the greatly increased production of cracked oils. These require, as a rule, more careful and elaborate treatment than do the natural products obtained from the non-cracking distillation processes. The other branch of petroleum refining is that concerned with lubricating oils. This is a difficult matter at best. It has always been costly and tedious and is becoming more so all the time due to the increasing exactness of the trade requirements.

The present paper is to be confined simply to the treatment of petroleum products with sulphuric acid. The neutralization of the acid oil and any subsequent processes are considered proper subjects for separate discussion. This is also true of such matters as the actual dosages used in practice in the acid-treatment of individual oils.

General Theory

All refining processes have as their object the removal of certain impurities in the oil which diminish and sometimes even destroy its commercial value. These impurities are either already present in the crude or else are formed during the distillation process. They are probably limited to organic bodies containing sulphur, oxygen or nitrogen. This would include the various asphaltic or bituminous substances that discolor the distillates, and sulphur alcohols, pyridines, etc., which give them an objectionable odor. The method of refining an oil, or treating it, as the chemical process is generally called, varies very much with the use to which the finished product is to be put. For instance, it would be wasteful to remove from an oil which is to be used exclusively as a gas engine fuel those substances which make an illuminating oil smoke or incrust the wick of a lamp. One of the most commonly used refining processes will now be considered in detail without reference to any particular kind of oil.

The Sulphuric-Acid Treatment Outlined

The use of sulphuric acid in refining petroleum distillates is almost as old as the oil industry itself. This acid was used in the refining of coal oil by Gower as far back as 1792 and was adopted by the petroleum industry about 60 years ago. Despite the many years that have elapsed since then, the chemistry of the sulphuric-acid treatment is still far from being fully understood. What takes place during the process is so complex that it taxes the imagination even to conjecture all the possible type reactions, much less actually to observe or measure them with any degree of accuracy. Much work has been done in the study of this process by many investigators and the results of some of this research are given here.

Very briefly put, the refining of distillates with sulphuric acid is accomplished by mixing the acid with the oil, generally in several doses, by means of air or mechanical agitation. The sludge, consisting largely of reaction products, is drawn off and the oil neutralized with caustic soda or other alkalis. It is finally washed with water to remove the excess of alkali and the alkaline reaction products, and the chemical refining is complete. In actual practice this system must be modified to suit the needs of the particular oil being treated.

At present let us study briefly the various hydrocarbons and other compounds found in petroleum, with particular attention to their behavior toward sulphuric acid, both concentrated and fuming. It may be pointed out that Gurwitsch[1] in his concise and classical volume "Wissenschaftliche Grundlagen der Erdölbearbeitung," has presented the theory of the reactions between sulphuric acid and the various hydrocarbon series in a very logical manner. Therefore his sequence of presentation will, in the main, be followed for this part of the discussion. However, in the light of more recent investigations, it is impossible to concur with him in all of his statements.

Paraffines and Naphthenes

When pure and under ordinary conditions, the paraffines and naphthenes do not react with or dissolve in either concentrated or fuming sulphuric acid. However, several investigators have succeeded in sulphonating naphthenes and normal paraffines with fuming sulphuric acid under special conditions in an experimental way. Both paraffines and naphthenes are quite freely taken up by cold sulphuric acid when they are mixed with other bodies which are themselves reactive with the acid. This is the condition that exists in actual practice, and in this way we account for the fact that an oil can be treated with one dose of acid after another until finally its volume is reduced sometimes as much as 80 per cent. Such is actually the case in the refining of water-white medicinal oil. It has not been established whether this consumption of paraffines and naphthenes is due to chemical reaction or adsorption. It is quite probable, though, that the non-reactive paraffines and naphthenes are mechanically

[1] Gurwitsch's work has recently been made available in English translation under the title of "The Scientific Basis for Petroleum Refining."

taken up—i.e., adsorbed, by the acid sludge. This sludge, a black viscous material, consists of the products formed when the acid reacts with certain constituents of the oil being treated.

Gurwitsch points out that the Imperial Russian Government required that the so-called asphalt content of petroleum products be determined by dissolving the oil in twice its volume of benzine and shaking with 20 per cent by volume of concentrated sulphuric acid. The increase in volume of the acid was taken as the asphalt content of the oil. He found that some residua showed more than 100 per cent of asphalt according to this test. On the other hand, however, after the benzine was distilled off, the acid-treated solution left a much larger percentage of oil as a residue than should have been the case considering the amount of "asphalt" adsorbed by the acid. For instance, a solution of 50 c.c. of residuum in 100 c.c. benzine was treated with 10 c.c. of sulphuric acid. Its volume decreased 28 c.c. The benzine was now distilled off. The oil remaining in the flask amounted to 36 c.c., not 22 c.c. as was expected. This, Gurwitsch feels, can be explained by assuming that the sulphuric acid removed not only certain constituents of the residuum treated but also 14 c.c. of the benzine. He proved this by diluting the acid sludge with water, neutralizing with soda lye and actually distilling off 14 c.c. of benzine. The same results were obtained when refined kerosene, consisting practically entirely of paraffines and naphthenes, was substituted for the benzine. All this certainly seems to point to an adsorption of the non-reactive hydrocarbons in the acid sludge.

Aromatic Hydrocarbons

Cold concentrated sulphuric acid attacks aromatic hydrocarbons only to a very slight extent and since nearly all technical sulphuric-acid treatments are given at atmospheric temperatures, one could scarcely expect to find true sulphonation of aromatics in the distillate taking place to any noticeable degree.

There are appreciable quantities of so-called sulphonic acids found in most sludges from ordinary cold acid treatments. Several authorities agree, however, that these in reality consist mostly of alkyl-sulphuric acids. Davis[2] found, for instance, that when the substances generally taken to be sulphonic acids are fused with caustic soda or potash no phenols are obtained. His particular work was done on bodies obtained from a California oil. Brooks and Humphrey[3] take exception to the views generally held and have pointed out that the higher benzene homologs are very readily sulphonated. Brooks and Bacon[4] have also shown that the fluorescent constituents of petroleum and its distillates are readily sulphonated by concentrated sulphuric acid, the result being the formation of fluorescent, water-soluble sulphonic acids.

The foregoing discussion applies only to concentrated sulphuric acid. If fuming acid is used at ordinary atmospheric temperatures, there is no question that sulphonation of aromatics goes on really vigorously and the sludge will show a yield of sulphonic acids corresponding to the percentage of aromatics in the raw distillate, provided, of course, sufficient acid was used to permit of the complete reaction. This effect is more pronounced when fuming acid is used at elevated temperatures. Edeleanu and Gané,[5] in their investigation of the sulphonation of petroleum distillates, treated various fractions of Bustenari kerosene with 12 per cent fuming sulphuric acid at 80 deg. C. The losses in treating ranged from 6.23 to 10.96, averaging 7.53 per cent. They distilled the sludges with superheated steam and recovered in the neighborhood of 4.6 per cent of aromatics. These included xylene, mesitylene, pseudocumene and many hydrocarbons of unknown constitution such as $C_{11}H_{16}$, $C_{12}H_{18}$, C_9H_{10}, $C_{11}H_{12}$ and $C_{12}H_{14}$. The various sludges contained widely differing percentages of aromatic bodies. In the middle fraction the substances taken up by the acid consisted of 86 per cent of aromatics. In the last fraction (b.p. 258 to 292 deg. C.) they yielded only 10.6 per cent. By converting the sulphonic acids into chlorides and sulphamides Edeleanu and Gané also succeeded in showing that the fuming sulphuric-acid sludge contained disulphonic as well as sulphonic acids. A typical body of this class is m-xylene-disulphonic acid.

Unsaturated Hydrocarbons

It is among the unsaturated bodies that we find the greatest single source of trouble in the chemical treatment of petroleum products. Of all the hydrocarbons found in petroleum distillates the unsaturated ones are undoubtedly the most readily attacked by cold concentrated sulphuric acid. Unsaturated hydrocarbons, either straight-chain or cyclic, are far from being objectionable as fuel. In fact, because of their high carbon content as compared with the saturated paraffines and naphthenes, they are more desirable for this purpose. After all, in one form or another, this is the principal use to which all the light petroleum fractions are put. Even as lubricants the complex unsaturated hydrocarbons are desirable, as their viscosity is greater than that of the saturated bodies of corresponding boiling point.

Now the chemical activity of the unsaturated hydrocarbons is unfortunate in two ways: (1) The ordinary sulphuric-acid treatment, necessary to remove the impurities, also removes a considerable amount of these perfectly good constituents of the distillate. (2) The reaction products of the acid with the unsaturated hydrocarbons remain in solution in the refined distillate. These reaction products are neutral esters of sulphuric acid together with alkyl-sulphuric acids similar to those mentioned in connection with the action of sulphuric acid on aromatics. In cases where it is necessary to redistill the acid-treated and neutralized distillate, these alkyl-sulphuric acids can and very often do cause an endless amount of trouble by breaking up into alcohols and free sulphuric acid. The neutral esters also decompose rapidly at 140 deg. C. or higher temperatures.[6] Decomposition takes place, to a certain extent, even at ordinary temperatures. The liberated sulphuric acid attacks the steel of the still and its dephlegmating and condensing system. The annoyance and cost of frequent partial or complete shut-downs of a still plant because of the decomposition of these reaction products are known to have doomed the commercial operation of an otherwise feasible cracking plant the distillates of which could not be refined commercially without a final redistillation. Several other plants are

seriously handicapped on this account at the present time, although they are commercially successful despite it.

The action of sulphuric acid on unsaturated hydrocarbons has been a moot question for many years. Until recently it was generally believed that sulphuric acid, especially fuming, would remove all unsaturated bodies from petroleum. The well-known analytical method of Kramer and Boettcher is based on this assumption. In this method unsaturated hydrocarbons are determined by shaking the oil with an equal volume of concentrated acid. While the conviction has gradually grown that figures obtained in this way are quite unreliable, it remained for Brooks and Humphrey[7] to prove this and to throw much valuable light on the complex chemistry of the unsaturated hydrocarbon-sulphuric acid reactions. These investigators state that the principal results of the action of sulphuric acid on the olefines are polymerization, the formation of secondary and tertiary alcohols and mono- and di-alkyl esters of sulphuric acid. None of the simple or mono-olefines which they studied yielded tars with concentrated sulphuric acids at 15 deg. C. This last statement is a direct contradiction of one of the long-established theories of oil refining. Brooks and Humphrey also found that with increasing molecular weight the tendency is toward polymerization, that the polymers are much more stable toward sulphuric acid than the parent olefines and that the more viscous and heavy polymers are found not in the acid sludge, but, to a large degree, in the oil layer. All the heavier olefines were found to be quite stable. The tars obtained in treating highly cracked oils are taken to be due to the presence of diolefines. Those obtained in the treating of lubricating distillates are also formed from diolefines and perhaps they may also be formed from a number of other substances.

Bituminous Substances

Very little is known about the constitution of those bodies which are responsible for the color in petroleum distillates. It is generally assumed that this color is due to the presence of bitumens. This belief is based on a certain amount of research work which has been done on this question but which so far has been entirely inadequate to establish anything but a number of widely differing theories. Even the nature of the effect which sulphuric acid has on bituminous bodies dissolved in petroleum distillates has been much debated. So, for instance, Schulz[8] explains the matter as being entirely an adsorption phenomenon. Ubbelohde,[9] on the other hand, considers the removal of these substances by sulphuric acid to be due to their precipitation from the oil, the acid serving merely as an agent to throw them out of colloidal solution. Gurwitsch[10] disagrees with both of these authorities and offers a number of excellent reasons for believing the reactions to be exclusively chemical, somewhat in the nature of a polymerization. It is not a polymerization in the ordinary sense of the word, according to this author, because an elementary rearrangement takes place, one result of which is the addition of sulphur to the polymerized molecules.

Despite our present ignorance of the exact chemistry or physics of the case, the fact remains that bituminous substances can be completely removed from petroleum by the action of sulphuric acid.

Organic Acids

Many crudes and their distillates contain organic acids of various sorts. Chief among these are the naphthenic and poly-naphthenic acids and the phenols. Markownikoff[11] found that an excess of concentrated sulphuric acid completely destroys oxygen-containing bodies such as these acids, also that the amounts of acid used technically are not large enough to bring about complete destruction of these substances. In fact both Zaloziecki[12] and Condrea[13] isolated naphthenic acids from acid sludge.

Any phenols present in unrefined distillates are not subject to the action of cold concentrated sulphuric acid any more than other aromatic bodies, with the exception of those homologs of high molecular weight. These, as has been pointed out previously, are likely to be sulphonated.

Sulphur Bodies

There are several objections to the presence of sulphur in petroleum products. The element is found in oil in two forms, as free sulphur and as a constituent of complex substances of several types, either gaseous, liquid or solid. The gaseous and liquid sulphur compounds are generally characterized by an unpleasant if not unbearable odor and by the corrosive action of their decomposition products. Frequently sulphur bodies are responsible for the straw color of light distillates.

It is a difficult matter to discuss the effects, actual and possible, of sulphuric acid on sulphur compounds. This is because there are so many of them and furthermore so little is known of their structure. There is absolutely no relationship between the percentage of sulphur in an oil and the type or intensity of treatment necessary to remove all or at least most of it. It has been necessary to employ special processes in refining some oils which are handicapped by large amounts of sulphur in forms which stubbornly resist removal by sulphuric acid. The well-known Frasch process is a typical example of a chemical treatment designed specially to remove sulphur from oil. Usually, however, sulphuric acid will sufficiently remove those quantities and types of sulphur bodies which occur in the average petroleum. The so-called "doctor treatment,"[14] which has become widely used in late years, serves very well to reduce the sulphur content and improve the color of light distillates. In many refineries it has entirely replaced the sulphuric-acid treatment as applied to gasoline.

Nitrogen Bodies

Practically all petroleums contain some nitrogen. In most oils it occurs in negligible quantities or in the form of compounds which are not objectionable. At times, however, the oil to be refined does contain nitrogen in a form which is very obnoxious. This is specially true of cracked gasolines.[15] Little is definitely known of the constitution of the nitrogen bodies occurring in petroleum and its distillates. Most of them seem

to be pyridine and quinoline bases and are removed by concentrated sulphuric acid. Sometimes, however, it is necessary to use very dilute acid. Other substances, such as metallic oxides, have also been effectively employed to free oil of nitrogen-bearing impurities.[16]

Factors Affecting Acid Treatment

Having considered, without going into detail, the chemistry of the sulphuric acid treatment, the next step leading to an understanding of the process is a review of those influences which may alter the final result.

The Constitution of the Oil

The kind of acid treatment to be used depends almost entirely on the constitution of the distillate. Several general rules may be formulated—viz.:

1. The higher-boiling the fraction the more rigorous the treatment necessary to obtain a certain color or degree of refinement.
2. The quantity of acid required decreases with the narrowness of the fraction.
3. Cracked distillates require more treatment than do the natural distillates.

Let us consider a typical case to show the relationship between the boiling-point range of a distillate and the quantity of acid used in refining it. Two fractions were cut from a California crude. One was a kerosene distillate with a gravity of 38.5 deg. Bé. The other was a lubricating distillate of 22.2 deg. Bé. Both were about equally narrow fractions and were to be refined to a water-white color. The kerosene was given a total of 23 lb. of fuming acid and 4 lb. of 66 deg. Bé. sulphuric acid per barrel. The lubricating distillate, on the other hand, received 335 lb. of fuming and 20 lb. of 66 deg. acid per barrel, and finally was filtered in order to get the water-white color.

Two oils may have almost identical physical constants and yet differ very greatly in their make-up. This is illustrated by two lubricating oils with the following physical properties:

Oil No. 1	Constants	Oil No. 2
476	Saybolt viscosity at 100 deg. F.	462
365	Open-cup flash test	380
425	Open-cup fire test	435
No. 6½	NPA color test	No. 6½
24	Cold test, deg. F.	20
18.0	Baumé gravity, deg.	19.7

Oil No. 1 is a heavy California motor oil which consists of a very large fraction of lubricating distillates reduced to the proper viscosity and flash test. Oil No. 2 is a widely used brand of motor oil, also made in California, and consisting of a quite narrow cut run to specification and treated without further reduction. As shown above, their tests are practically the same. Yet Oil No. 2 requires only an average of 31 lb. of acid per barrel for treatment, while No. 1 requires 47 lb. Neither of the oils is filtered. Both are the product of combined fire and steam distillation in conventional cylinder stills manipulated in practically the same manner.

Cracked motor fuels invariably need treatment to remove objectionably smelling compounds. Also, they usually acquire a dark color quite rapidly when exposed to air. These oxidation products or the bodies from which they are formed must also be removed in order to give the distillate a marketable color or rather lack of color. On the other hand, most motor fuels which are not cracked, such as straight-run gasoline, for instance, can be sold as finished products directly after distillation and without chemical treatment. If a chemical treatment is given it consists of just a small amount of sulphuric acid or perhaps only an agitation with sodium plumbite solution.

Cracked gasolines are hard to refine as compared with the natural product. Fortunately, due to lessened use and an increased supply of crude, it is no longer necessary to make cracked kerosene, at least in the United States.

Lubricating distillates are difficult to treat when in the best of condition. Cracked lubricating oils require a great deal more acid to bring them to a stable color than do those distillates in which cracked products are at a minimum. In fact, it is often absolutely impossible to refine a badly cracked lubricating oil.

Strength of Acid Used in Treatment

While it is true that sulphuric acid in relatively dilute form (not less than 65 per cent H_2SO_4 or 52 deg. Bé.) can be used successfully in the treatment of certain distillates, it has become general practice in the industry to work principally with two concentrations. Sulphuric acid of 66 deg. Bé. (sp.gr. 1.84 or 167 deg. Tw., 93 per cent H_2SO_4) is used in refining most of the world's petroleum. In special cases 98 per cent sulphuric acid (sp.gr. 1.850) is used. This has been found to be better than 66 deg. acid for the refining of certain California distillates, particularly lubricants. In the making of high-grade kerosene or of water-white medicinal oils fuming sulphuric acid is used. This is generally of the 15 per cent SO_3 form (about 103 per cent H_2SO_4), although acid with 20 per cent free SO_3 is sometimes used. There have been developments within recent years of the use of SO_3 gas directly from the acid plant, but this could certainly not be called general practice.

There are two reasons why acids of such high concentrations as those just mentioned are used. In the first place, the quantity required to achieve a certain result in refining increases very rapidly the lower the concentration. Secondly, the more dilute the acid the more troublesome it is to ship and store. In fact, as is well known, sulphuric acid of less than 60 deg. Bé. cannot be shipped commercially in iron tanks.

The relation of acid concentration to results obtained is well illustrated by the following figures. A partly cracked distillate (sp.gr. 0.8245) was treated with acids of various concentrations. In all cases the temperature was 64 deg. F. at the start. The amount of acid used in each treatment was 2.5 per cent by weight.

Tests on Oil After Treatment	Strength of Acid in Per Cent H_2SO_4 — 70	93	96	99	103 (15 Per Cent Fuming)
Saybolt, color, inches	10.5	17	20	25	22
Iodine No., Wijs	16.3	7.2	2.6	1.3	0.65
Doctor test	Sour	Sour	Sweet	Sweet	Sweet

It is clear from the above table that the refining action increases much more rapidly than the concentration of the acid. The only figure which is out of line is the darker color obtained with the fuming acid (103 per cent H_2SO_4) as compared with that given by 99 per cent acid. This is often found to be the case and can be readily explained. Fuming sulphuric acid acts primarily by sulphonating and oxidizing unstable hydrocarbons rather than by polymerizing them. Many of these sulphonation products are soluble in the oil and consequently impart to it a darker color. As these products are more readily soluble in concentrated sul-

[16] In this connection consult Mabery and Hudson, *Am. Chem. J.*, vol. 25, p. 253 (1901); also Brooks and Humphrey, *J. Am. Chem. Soc.*, vol. 40, No. 5, p. 848 (1918).

phuric acid than in oil, the practice has been developed of agitating with a small amount of 66 deg. Bé. acid (93 per cent H_2SO_4) an oil which has been treated with fuming acid. In this way excellent colors can be obtained.

Use of Sludge and Regenerated Acid

Only a part of the acid used in refining is used up in the process. For instance, a sludge from a typical California kerosene treatment with 66 deg. Bé. acid had a Baumé gravity of 46.0 deg. (sp.gr. 1.47) and contained 64 per cent of H_2SO_4 and 24 per cent of hydrocarbons. The sulphuric acid from such sludges is often regenerated and used for various purposes.

Where the fresh acid is given in several doses to the oil being treated and the sludge is drawn off after every agitation, the last one or two drainings frequently consist of fairly pure and concentrated acid. These drainings can be used to advantage in treating the next batch of oil, either as so-called "water acids" to remove any moisture in the oil or as a first dose of "acting acid" to aid in the refining.

Regenerated acid—that is, sludge acid from which water and organic substances have been removed as far as possible—does not usually lend itself well for further use in refining except in the manner indicated above for relatively clean sludge. At the present time considerable work is being done on the subject of acid recovery. Several very clever processes have come into use and the near future will probably see a commercial and generally acceptable method for making a really pure regenerated acid.

Impurities in Sulphuric Acid

Nitrogen trioxide (N_2O_3), nitrogen pentoxide (N_2O_5) and selenium dioxide (SeO_2) have been found to be injurious impurities in sulphuric acid used for oil refining. Schulz,[17] the authority for the foregoing, goes into detail regarding the effects of various concentrations of these impurities. Kharitchkoff[18] also condemns the presence of nitrous and nitric acids and considers 0.05 to 0.07 per cent the maximum permissible. Bacon and Hamor,[19] after also quoting Schulz and Kharitchkoff on the effects of impurities, laconically add that acid-storage tanks in refineries should be subjected to periodical cleaning.

American commercial sulphuric acids are made in many degrees of purity. Analyses of several standard makes of contact acid showed the greatest impurities to be iron sulphates, sometimes also slight amounts of HCl and H_2SO_3. Traces of arsenic, lead and selenium were found in some of these acids. Nitric acid as an impurity is found only in lead-chamber acid. Contact-process acid made from brimstone is generally very pure. Below are typical analyses of acids supplied to southern California refiners by a large manufacturer:

	66 Deg. Bé. Acid	99 Per Cent Acid	15 Per Cent Fuming Acid
Sulphuric acid, per cent	93.30	98.96	103.48
Iron, per cent	0.0056	0.0017	0.0031
Sulphur	Nil	Nil	Nil
Lead	Trace	Trace	Trace
Zinc	Nil	Nil	Nil
Selenium	Nil	Nil	Nil
Arsenic, per cent	Nil	0.00001	Trace
Nitrogen compounds	Nil	Nil	Nil

This same concern makes a commercial acid for the United States Navy so pure that it can be used as an electrolyte when diluted.

[17] *Chem. Zeit.*, vol. 35 (1911), p. 1129.
[18] *Westnik shirow. westsch.*, vol. 6 (1905), p. 119.
[19] *Amer. Petroleum Industry* (1916), p. 583.

Finally one cannot help but feel that while certain difficulties in refining might possibly be laid to inorganic impurities in the acid, there are at least half a dozen other factors in the acid treatment which are more likely to account for these troubles.

Quantity of Acid Used in Treating

The desired results in refining with sulphuric acid cannot be obtained simply by using larger and larger quantities of acid. There is a very definite limit beyond which it is no longer feasible to use additional amounts of acid. This limit is set by the following considerations:

(1) The refining power of the acid is not proportional to the quantity used. In fact, it diminishes very rapidly, as is shown by figures obtained in the treatment of a California lubricating distillate from Coalinga crude:

66 Deg. Bé. Acid Used (Percentage by Weight)	Color of Finished Oil (NPA Scale)
5	5
10	3
15	2
20	1½
50 (including 30 per cent fuming acid)	1

(2) If too much acid is used the distillate is apt to be "burnt." By this the practical refiner means that the treatment has been so rigorous that those delicate and probably aromatic compounds which give a pleasing "outer-tone" or fluorescence to the oil have been destroyed. This applies mostly to lubricating oils, since in refining light distillates one of the principal objects is to remove all trace of color, even of "outer-tone." An acid-burned oil generally has a dirty, brownish or bluish tinge.

(3) The more viscous the oil the more liable it is to the formation of emulsions. These emulsions are usually the result of a heavy acid treatment. An emulsion is a serious problem and when broken almost always yields a darkened oil and a large loss.

Use of the Acid in Doses

It is general practice to apply the acid used in treating in several doses. There are several very good reasons for this. In the first place, most oils are treated at as low a temperature as possible. If sulphuric acid, especially fuming, is mixed with the oil in large quantities the heat of reaction will probably raise the temperature too high. Secondly, most distillates contain a certain amount of free water or at least moisture. If this should be permitted to dilute all the acid, its effectiveness would be materially reduced. Therefore the first dose, or "dump," as it is generally called in practice, is used to remove this water. The succeeding doses can then act on the oil at their original concentration. Thirdly, aside from the question of dilution by water it has been found that a fixed quantity of acid has considerably greater refining power when applied in several small doses rather than in one large one. Since the action of the acid on the oil is partly a solvent action, this behavior is in keeping with the well-known physicochemical principles of solutions.

In speaking of applying the acid in several doses it is assumed, of course, that the sludge is drawn off after each dose has been agitated. Otherwise the final effect would be quite the same as when the acid is given all at once.

Gurwitsch thinks that the good effect of giving the acid in fractional portions is probably due to the fact

hat sulphuric acid often reacts in several stages with he asphaltic and unsaturated compounds of high molecular weight. Even at the beginning or first stage reaction products are precipitated from the oil. In refining certain petroleum products he noticed that even with the addition of small amounts of acid a very weakly acid sludge separated out. Most of this is soluble in benzine. If this sludge is treated with additional quantities of sulphuric acid, it loses its solubility n benzine almost entirely. Now, on the other hand, if he raw (unrefined) product is treated with a single iberal dose of acid, the same insoluble sludge is formed. In cases like this it is very easy to see that the use of acid in several doses must be more effective than a single dose. In the latter case some of the acid performs the entirely useless work of changing still further he reaction products which have already separated rom the oil.

The Effect of Temperature

The temperature at which the acid treatment is carried out is an extremely important matter. A general rule followed by most refiners is to treat at just as low a temperature as possible. This rule is based on the fact that one of the principal objects in refining most petroleum distillates is to make them as nearly colorless as possible, and this can best be done at low temperatures. The lack of color in an oil does not necessarily ndicate a high degree of refinement. However, the rade is prone to judge an oil by its appearance and often blindly assumes that the best looking oil is really he best. This is equally true of light oils such as motor fuels and of lubricating oils.

The only exceptions to this rule of treating at low emperatures are kerosene and sometimes steam-cylinder oil. If a really high-grade kerosene is desired it should be treated hot, as the sulphonating power of the acid increases rapidly with the rise in temperature and aromatic bodies must be removed as completely as possible. The removal of unsaturated hydrocarbons and bituminous substances is also accelerated by the hot reatment. The color of hot-treated oils is generally poor, and this defect is remedied by an after-treatment at relatively low—i.e., atmospheric—temperatures with 66 deg. acid or by filtration through bone black or other decolorizing material. When treating steam-cylinder oils there is an entirely different reason for treating it hot. The object is to reduce sufficiently the viscosity of the oil to make treatment possible. Beyond this any excess heating is carefully avoided. It might be argued hat it is not necessary to treat cylinder oils or other heavy lubricants in their natural condition, the practice usually being to dilute them with a light naphtha sufficiently to reduce the viscosity and then to remove he naphtha after treatment or filtration. This is true, ut not always feasible. There are steam-cylinder oils made which will not stand the distillation after treating necessary to remove the admixed naphtha and such oils must necessarily be treated hot.

Zaloziecki,[20] as a result of his study of the acid treatment of a Galician kerosene, published the table given n Table I.

This table is self-explanatory. Zaloziecki interprets the nsatisfactory color obtained at elevated temperatures n the following manner: Colored oxidation products re freely formed at these temperatures and reactions resulting in the formation of free water are accelerated. The result of the latter is a dilution of the acid, and this in turn causes certain oil-soluble asphaltic substances to pass out of the acid solution into the oil and thus discolor it.

[20] *Chem. Zeit.* (1895), p. 875.

The Effect of Light

Possible effects of light on the results of acid treatments are disregarded in technical procedures. Acid lubricating oils darken rapidly on exposure to direct light, while the same oils darken only very slowly in diffused light or darkness. Zaloziecki found that the acidity was higher and the color darker when a Galician kerosene was treated in diffused light than when it was treated in the dark.

TABLE I—STUDY OF ACID TREATMENT OF A GALICIAN KEROSENE

Temperature, Deg. C.	Acid Sludge, Grams	Unused H_2SO_4	Sulphonic Acids Calculated as H_2SO_4	Acidity of the Kerosene in Terms of H_2SO_4	Polymerization Products	Color in mm. as Compared With an Arbitrary Glass
0	61.6	47.91	1.45	0.86	5.25	193
5	62.0	46.82	1.55	1.42	5.02	166.5
10	62.5	46.53	1.65	1.56	5.13	143.0
15	63.5	45.72	1.93	1.76	5.40	112.5
20	64.3	44.37	2.22	2.45	4.93	89.5
25	64.8	43.52	2.68	2.63	5.62	80.5
30	65.2	41.87	3.72	3.65	5.43	52.0

40	66.0	39.03	5.62	4.83	5.78	Straw
45	66.4	38.62	5.76	5.62	5.21	Straw
50	67.0	37.26	4.81	5.91	4.81	Straw

Method of Mixing Acid and Oil

Three methods of mixing chemicals with the oil being treated are used in practice. The one used originally was mechanical and is illustrated by the gear-driven paddles used in grease kettles. Mechanical agitation is at present used only in special cases, mostly when oxidation by air is to be avoided. In most treatments the acid is now mixed with the oil by means of an air blast. In this way rapid, thorough and relatively cheap diffusion of the acid through the oil is obtained. Air agitation, however, has its drawbacks. First, it oxidizes the oil. This is a serious consideration in the case of cracked distillates or oils being treated at elevated temperatures. Second, the air almost always contains considerable water. This dilutes the acid and greatly reduces its efficiency. Third, when light distillates are agitated with air, the evaporation losses are prohibitive. Consequently oils like gasoline are mixed with the acid or other substances by means of a circulating pump. This takes suction near the top of the agitator and pumps the oil in at the bottom.

The Time Factor in Treating

The length of time required to utilize the full refining value of the acid depends on a number of modifying circumstances. Among these the most important are: (1) Method and violence of agitation. (2) Size and shape of the apparatus. (3) Viscosity of the oil. (4) Quantity of acid used and number of dumps in which it is applied to the oil.

When the oil is being treated in separatory funnels in the laboratory, a few minutes violent shaking by hand generally suffices. In agitators of 500-bbl. to 2,000-bbl. capacity light distillates are usually agitated by air for periods varying from 15 minutes to 1 hour. If circulation by pump is used as a method of mixing, the time is increased to as much as 16 hours or more.

The time limit in acid-treating lubricating oils may be defined more closely. It is safe to say that the average large-scale batch varying, say, from 25 to 1,200 bbl. cannot be intimately mixed with acid in less than half an hour. Complete mixing should be attained in 2 hours, at any rate. Needlessly prolonged contact between the acid and the oil is harmful. This is because part of the sludge will dissolve in the oil and thus discolor it. Also, long agitation of acid lubricating oils frequently results in emulsions after the addition of an alkali solution as in the ordinary method of treating. While this is true no matter by what means the oil is agitated, it must be borne in mind that the influence of air is especially bad because of its oxidizing effect.

For a long time the separation of the acid sludge from the oil in which it is suspended was a serious problem in oil refining. Of course, the light oils have such a low viscosity and specific gravity that the heavy viscous sludge settles out almost immediately. Such, however, is far from being the case with lubricating oils, especially the more viscous ones.

Formerly the oil was freed from sludge either by long settling or by centrifuging. The former method injured the oil because of the length of time in which it had to remain in the acid condition. The latter procedure was very expensive and the lead-lined centrifuges used were constantly in need of repair.

During the last 25 years it has become universal practice to "knock down" the sludge from the acid-treated oil. This practical expression really means that the very finely divided sludge particles are gathered together into nodules sufficiently heavy and compact to settle out of the oil. This result is accomplished by sprinkling cold water or caustic-soda solution on the oil while agitating it very gently. Before the sludge is "knocked down" the oil has a color ranging from blue to purple. The oil is more purple when it has been treated with a large amount of acid. After all the sludge is gathered and precipitated the oil takes on a color ranging from green to yellow. The acid treatment is now complete and the oil is ready to be neutralized.

Los Angeles, Calif.

Mechanism of Metallic Oxidation at High Temperatures*

Rapidity of Corrosion in Heated Atmospheres Is Not Determined by Any Property of the Metal but by Some Combination of Physical Properties of the Oxide and Its Ability to Absorb and Diffuse Oxygen

By N. B. Pilling and R. E. Bedworth

Research Laboratory, Westinghouse Electric & Manufacturing Co.

THE corrosion of metals is one problem of great economic interest upon which much time and thought have been expended over a period of many years. In the effort to avert the destructive action of a hostile environment, attention has naturally been directed almost entirely upon the conditions under which an overwhelming majority of metallic structures are called upon to perform, and the extensive and complicated phenomena attending the corrosive action of atmospheric agencies, acting at the ordinary atmospheric temperatures, have been studied voluminously, although a unanimity of opinion regarding many fundamental facts in the mechanism of corrosion is even now far from being reached.

One somewhat neglected type is the corrosive action of various gases upon metals when exposed to temperatures considerably higher than the atmospheric range, and more especially the attack of atmospheric oxygen upon exposed metallic surfaces. That the problem is a difficult one to contend with is connoted by the practical dominance of industrial electric heating by alloys of one type (nickel-chromium). Proprietary interest may account in part for the paucity of information publicly available in the technical literature upon even the most general factors determining the behavior of metals and alloys exposed to such exacting conditions.

The present brief paper is an account of some conclusions reached as the result of experimental work extending over several years; it is unburdened of much perhaps desirable experimental detail and proof.

High-temperature metallic oxidation may be considered as a phase of metallic corrosion. The scheme outlined below, in which corrosive agent and environment are the principal criteria, is one way of analyzing the several groups of corrosion phenomena.

Erosion:
  Disintegrating or destructive action by *physical* causes
Corrosion:
  Disintegrating or destructive action by *chemical* causes
  Low-temperature corrosion:
    Solid participating phases essentially immobile.
      Gaseous agent.
      Liquid agent.
        Action electrolytic.
        Action non-electrolytic.
  High-temperature corrosion:
    Solid participating phases possess diffusive mobility.
      Liquid agent.
      Gaseous agent.
        Reducing gases.
        Oxidizing gases.
          Water.
          Miscellaneous elemental and combined.

With the exception of the division between high- and low-temperature action, the classification is obvious enough. High and low are only relative terms, with no boundary between them. Similarly, there is no reason for the statement that diffusion is inoperative at certain low temperature; but there is an essential difference due to the fact that when the temperature is raised sufficiently the forces of diffusion not only become active, but active with such rapid amplification as to become dominant forces. The diffusive mobility of the solid constituents of alloys when highly heated is a property recognized by every metallurgist, and some of the fundamental operations of physical metallurgy, such as the heat-treatment and cementation of ferrous alloys, rest upon it as a foundation. The solution and diffusion of gases in solids are appreciated by all who have had occasion to handle hot hydrogen.

*A paper presented before the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers, Rochester, June, 1922.

Noble and Base Metal

Oxidation is a chemical reaction, and a reversible one —that is, in the presence of oxygen at a sufficiently high temperature, a metal may be oxidized, or its oxide decomposed, by suitably adjusting the pressure (concentration) of the oxygen atmosphere. At pressures greater than the equilibrium dissociation pressure of the lowest oxide, oxidation occurs; at lower pressures the oxide decomposes and the metal is unchanged in contact with free oxygen. This dissociation pressure is not a constant, but increases with rising temperature somewhat after the fashion of vapor pressures. Silver and palladium are standard examples in which at atmospheric pressures oxidation occurs at low temperatures and reduction at higher ones.

The first great division in the behavior of the metals may be made on the basis of the order of magnitude of the dissociation pressure of the lowest oxide, serving to separate the noble from the base metals. The former fall within the range of atmospheric pressures and above; the latter are extremely minute—e.g., at 1,000 deg. C. the dissociation pressure of cuprous oxide is estimated[1] to be of the order of ten-millionths of an atmosphere. Included in the few metals which may be classed as non-oxidizing by this distinction are gold, platinum, rhodium, silver, palladium and some chemically similar metals.

Dense Oxide Films Impede Corrosion

The base metals—the oxidizing metals—comprise the remainder of the common metallic elements, and a second division may be made among them based on the physical texture of the oxide which is formed. Here the determining factor is one of relative metallic and oxide density. As the surface of a metallic wire, for example, is being oxidized a cylindrical shell of metal is replaced by a cylindrical shell of oxide, which may or may not take up more space than the former. The characteristic of the formation of subsequent layers of oxide depend upon which of these conditions is fulfilled. If the layer of oxide formed takes up more space than the volume of metal which was oxidized to produce it, the oxide layer forms a tight fitting, solid sheet; if the reverse is the case, there is more space available within the original metallic dimensions than the oxide density requires, and a porous, bricky structure is the result. In the former case, the enveloping oxide layer may impede further oxidation; in the latter, by virtue of its porosity, it does not. The critical density ratio is given in the expression

$$\frac{Wd}{wD}$$

in which

W = molecular weight of oxide formed.
w = formula weight of metal.
D = density of oxide formed.
d = density of metal.

The cellular oxide structure results when this ratio is less than unity; the solid crystalline oxide when it exceeds unity. Table I gives values for this critical ratio computed from data available in current physical tables.

Those metals which fall into the cellular oxide structure group comprise most of the so-called light metals, and the characteristics of oxidation of the group have been confirmed experimentally with magnesium and calcium. Wires of these two metals heated in dry oxygen below their ignition temperatures (about 525 deg. C.) form oxide coatings the thickness of which increases directly proportionally to the time of oxidation—that is, the formation of an oxide film does not interfere with the speed at which subsequent films are formed. After complete oxidation of a calcium wire, the resulting lime wire had the same micrometer diameter as the initial metallic diameter, and from the known densities of calcium and calcium oxide it appears that 45 per cent of the volume of this lime wire was void. A steady stream of oxygen will pass through this porous layer to the oxidizing metallic surface without detectable impedance; expressed differently, the oxygen pressure gradient through an oxide coating of this type is zero.

The remaining large group, which is composed of the majority of the common metals, form compact enamel-like jackets of oxide, being free to expand outward as they form, and all exhibit the common property of suffering a progressive decrease in rate of oxidation at constant temperature, proportional to the thickness of the layer of oxide formed. This leads at once to a parabolic relation between time and quantity of oxidation, the square of the weight of oxide formed per unit of surface being proportional to the time of oxidation. Quantitative verification of this fact has been obtained with copper, iron, nickel, zinc, lead, cadmium and aluminum. At any time the rate of oxidation is inversely proportional to the thickness of the layer of oxide then on the surface. The fact that this rate varies quantitatively with the amount of oxide overlying the metal surface points to an important conclusion: that the speed of the reaction is not determined by any property of the metal at all, but is determined by some combination of physical properties of its oxide. To explain the known differences in the behavior of the metals as regards high-temperature oxidation metallic properties may be forgotten, but a knowledge of the characteristics of their oxides is imperative. It is unfortunately the case, as will appear later in this discussion, that the determinative properties are of a type in which quantitative information at the present time is almost wholly lacking.

TABLE I—CRITICAL DENSITY RATIOS OF METALS AND THEIR OXIDES

Metal	Ratio	Metal	Ratio
Aluminum	1.28	Manganese	2.07
Barium	0.78	Nickel	1.68
Cadmium	1.32	Potassium	0.51
Caesium	0.42	Silicon	2.04
Calcium	0.78	Sodium	0.32
Chromium	3.92	Strontium	0.69
Cobalt	2.10	Thorium	1.36
Copper	1.70	Tin	1.33
Iron	2.06	Tungsten	3.30
Lead	1.31	Zinc	1.59
Lithium	0.60	Zirconium	1.55
Magnesium	0.84		

Solubility of Oxygen in Oxide Layers

The way in which the oxide layer limits the rate of oxidation can only mean that the transmission of oxygen through this layer to the reaction surface, which is the juncture of metal and oxide, is effected against a resistance which is proportional to its thickness. For many reasons it appears that this transmission must be accomplished by the actual solution of oxygen in the metallic oxide, and its diffusion while in the dissolved condition from the outside to the inside sur-

[1] W. Stahl, *Metallurgie*, vol. 4, p. 682 ((1907).

face. The motive force of diffusion is difference in concentration, and speed of diffusion is determined by: (*a*) the concentration gradient of the diffusing substance, (*b*) the diffusional resistivity of the obstructing medium.

In the case of metallic oxidation, the concentration of free oxygen at the reaction surface is maintained at or very near to a value corresponding to the oxide dissociation pressure; at the outer surface it is that of the maximum solubility of oxygen in the oxide, and the difference between the two is the operating force causing a steady stream of free oxygen to pass through.

The critical oxygen pressure which we interpret as bearing a close relation to maximum oxygen solubility may be determined by rate observations in oxygen atmospheres of varying tenuity,[2] and the diffusional resistivity deducted from it and the diffusion rate. In Table II a comparison of the critical constants for three metals is given for a temperature of 900 deg. C.

TABLE II—CRITICAL OXIDATION CONSTANTS FOR THREE PURE METALS

	Electrolytic Copper	Electrolytic Iron	Electrolytic Nickel
Rate of oxidation g./sq.cm./hr.	0.000127	0.00065	0.00000076
Diffusional resistance of oxide (arbitrary units)	2,840	310	50,000
Critical oxygen pressure mm. Hg (maximum solubility)	0.36	0.20	0.04

Nickel at this temperature is 165 times as resistant to oxidation as copper, and this is due both to an oxygen solubility one-tenth as great, and a resistance to diffusion seventeen times greater, of nickel oxide as compared with cuprous oxide.

Rate of Oxidation at Elevated Temperatures

The way in which the rates of oxidation change with temperature, according to our previous analysis, is equivalent to the temperature change in diffusivity of oxygen through oxide, inasmuch as the corresponding change in oxygen solubility appears to be slight. The quadratic rate constant (isothermal) for all of the metals we have examined is related to the temperature of oxidation according to the type equation

$$k = AT^n,$$

a parabolic equation in which

k is the rate constant,

T is the absolute temperature, and

A and n are characteristic constants.

The shape of the curve is determined by the value of n, which is different for the several metals, but always fairly large, usually between 10 and 20. The rate of oxidation thus changes very rapidly with temperature; but the very generality of the equation makes a simple comparison between two metals difficult, except in the very special case, which unfortunately is quite unlikely, when the exponents are equal. Thus the ratio between the isothermal oxidation rates of two metals varies with temperature and may even reverse in relative magnitude.

As to the fidelity with which metallic oxidation follows this simple law, we can only say that in the case of copper, experimentally observed points in the temperature range of 400 to 1,000 deg. C. lie on this curve with surprising closeness, although at temperatures of 600 deg. C. and below there are deviations in the direction of faster rates, which approach the theoretical rates as a lower limit. The cause for this deviation is apparently due to fissuring of the protective oxide coating by the expansive action of the formation of new underlying oxide layers, and the failure of the original oxide surface to accommodate itself to the expansion on account of insufficient plasticity.

Aluminum and cadmium behave in an anomalous manner in that oxidation proceeds according to the parabolic law as is required by their density ratios, until an oxide coating which is truly hardly more than a film is formed, whereupon further oxidation ceases. At a temperature of 600 deg. C. this film forms upon aluminum in about 60 hours, and further exposure up to 900 hours brings about no increase. This critical oxide film weighs about 0.00010 gram per square centimeter, corresponding to a thickness of 0.00002 cm.

[2]For instance, if metallic wires are oxidized in oxygen at various pressures, the rate of oxidation is but slightly influenced by the gas pressure as long as the latter is below a certain value ("critical oxygen pressure"), but is directly dependent at higher gas pressures.

The Romance of Helium

The story of helium, its discovery, development, uses and methods of production is told in a recent Bureau of Mines bulletin by R. B. Moore, chief chemist. In the words of the report, the story of helium is one of the romances of science. It is one of the best examples of a discovery in pure science that has wide commercial application. In 1868, an eclipse of the sun was visible in India. Several scientific men who were in India making observations of the eclipse turned a spectroscope for the first time on the solar chromosphere—that part of the atmosphere of the sun, about 10,000 miles deep, which merges into the corona. A bright yellow line was observed and was thought at first to be due to sodium. Janssen showed, however, that this line was not just the same as either the D_1 or D_2 line of sodium, although it was extremely close to these lines, hence he suggested that the new line have the designation D_3. Frankland and Lockyer decided that D_3 was due to an element in the sun not previously discovered on the earth and suggested for it the name Helium from the Greek word *Helios*, the sun.

For several years nothing more was done in connection with this element. In 1894, Sir William Ramsay, in conjunction with Lord Rayleigh, made his memorable discovery of argon in the atmosphere, which was announced at the British Association meeting in the same year. After this discovery, Ramsay looked for other sources of the element. Through Sir Henry Miers, he learned that W. F. Hillebrand, of the United States Geological Survey, had obtained an inert gas from certain uranium minerals which he had decided was nitrogen. Ramsay, believing that part of it might be argon, obtained from Hillebrand a sample of the mineral, cleveite and after extracting gas from the mineral and purifying it, he ran it into a spectrum tube. The lines obtained were, however, different from those of argon. Among them was the bright yellow line noted by Janssen. Thus was terrestrial helium discovered.

Possessing great lifting power and being non-flammable, helium is recognized as superior to hydrogen for use in dirigibles. Another advantage of the gas for this use is that it diffuses through a fabric at about three-quarters the rate of hydrogen; its non-flammability makes it possible to place the engines in the framework of the dirigible, thus getting a direct drive giving greater control of the craft and much increased speed for any given horse power.

The bulletin also describes manufacturing processes.

Heating Coke Ovens With Blue Water-Gas

Blue Water-Gas Heating Doubles Surplus Gas From Ovens, Eliminates Carbon From Heating Flues and Permits Uniform Oven Operation, Without Change of Oven Burners or Other Parts of Fuel-Gas System

By J. F. O'MALLEY
Superintendent of Gas Manufacture, Empire Gas & Electric Co.

THE Empire Gas & Electric Co., of Geneva, N. Y., recently encountered a serious threefold problem. First, it was necessary to provide additional gas-producing capacity. Second, the plant must be made flexible to the point where coke production could be made to fluctuate as nearly as possible with the demand. Third, the necessity of stocking thousands of tons of coke in excess of requirements with a sluggish coke market showing little prospect of immediate improvement must be avoided. All these results were accomplished through the erection of a blue water-gas plant to supply fuel gas for heating the byproduct coke ovens, in place of using lean oven-gas as had been the former practice. The adoption of this blue-gas for heating has in fact practically doubled the surplus gas-producing capacity of the plant; and, in addition, it gives a greater flexibility of operation than could previously be obtained.

Advantages of Separate Heating Gas Supply

In operating a byproduct coke plant for the production of fuel gas, where several communities depend upon the plant for gas for their daily needs, it is necessary to maintain a sufficient supply to meet these needs and also to anticipate future demands of an ever-increasing gas consumption. It is also necessary under these conditions to maintain a quality of gas which conforms with the required standards. The coke produced must be of first-class quality so that it may find a ready market. This last is particularly germane in a plant where gas is the principal product, as the coke from such a plant must compete with that from plants where coke production is the prime consideration.

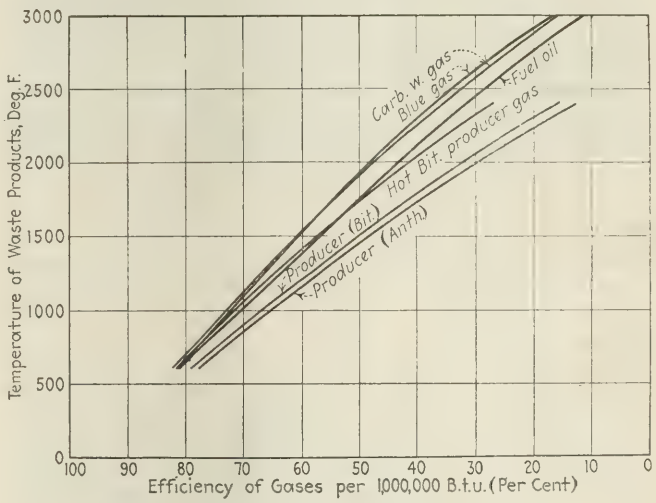
Where lean gas is used for heating the ovens and only the surplus of rich gas is sold, the operation is of necessity a balanced one. Both the lean and the rich gas must come from the coal charged. If the coal charging is interrupted for any reason, the gas production will automatically fall off, which results in a shortage of surplus gas and also of heating gas. As a result it is often a case of "robbing Peter to pay Paul" for a time, while "green" ovens are pushed to build up the gas supply and a poor quality of coke results.

These are the problems that make successful byproduct coke plant operation difficult and at times almost impossible, especially where a plant has gone through many years of service, and repairs and replacements are of frequent occurrence. A blue-gas plant, being an entirely separate gas-making unit using coke as fuel, fits into this situation exactly. And even though other conditions remain the same, if such gas is used to supply the ovens, it liberates an equal amount of oven-gas for sale as fuel.

The advantages of having a separate source of supply for heating gas which can be started and stopped on short notice is evident, for with it heats can be maintained irrespective of oven conditions much better than when the lean gas is used for heating. For such a separately generated gas, blue water-gas is much superior to producer-gas in that it has a higher flame temperature. Producer gas, having a greater percentage of inerts, must necessarily give a flame of lower temperature.

Additional Advantages Obtained

In addition to adding increased production of salable gas to the plant's output, there are other advantages, depending largely on local conditions, which may be realized from such a separate source of heat. It may be used to regulate the coke production more closely to suit market conditions and thus prevent the accumulation of large stocks. This is done by operating only enough ovens to take care of the gas requirements, using all oven-gas for outside demand and heating with



THEORETICAL COMBUSTION EFFICIENCIES OF VARIOUS GASES

blue-gas made from the coke. The coke production can be cut practically in half in this way.

The blue-gas auxiliary also permits the use of coals containing smaller amount of volatile than could be used without its aid. Thus coals especially suited for making foundry coke, may be employed in a plant where gas is the principal product, even though these coals are low in volatile. There are also times when high-volatile coal is difficult to obtain, and here again the low-volatile coal can be used and still sufficient gas be obtained.

Again, by the use of the blue-gas auxiliary, the total coal which must be carbonized for a given output of gas to consumers is greatly lessened. In times of coal shortage, when the only consideration must be to keep the supply of domestic gas at its normal level, this fact allows the storage pile to cover a longer period and may

be of great aid in saving the communities served from serious hardships.

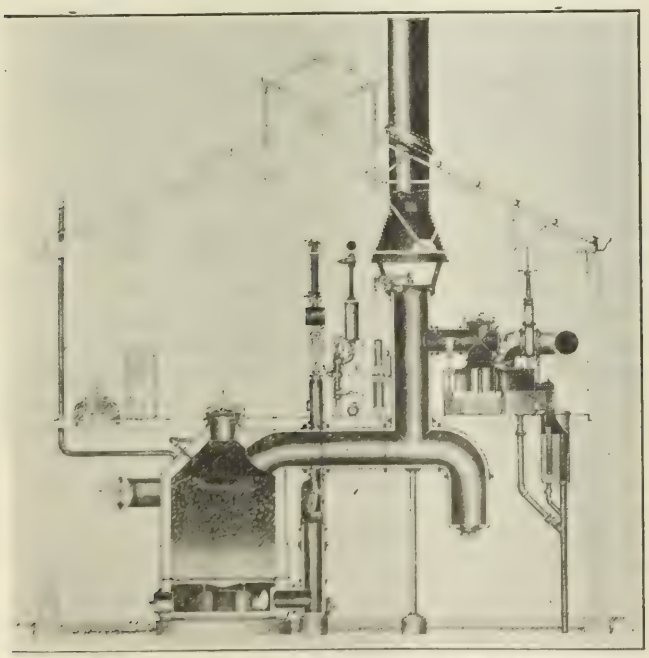
Description of Plant of Empire Gas & Electric Co.

The Empire company's gas plant consists of forty-six byproduct coke ovens of Semet-Solvay design and construction. Thirty of these ovens are four flues high, 15½ in. to 17 in. wide from pusher to coke side, 35 ft. long, and have a capacity of 7 tons each per charge. The sixteen ovens remaining are five flues high, 15½ in. to 17 in. wide, 35 ft. long, and have a capacity of 10 tons each per charge. These ovens are of the usual silica brick construction. Operating at approximately 20 hours average coking time, they carbonize 425 tons of coal per day, giving a total gas yield of over 4,000,000 cu.ft., of which 2,000,000 can be considered as surplus gas.

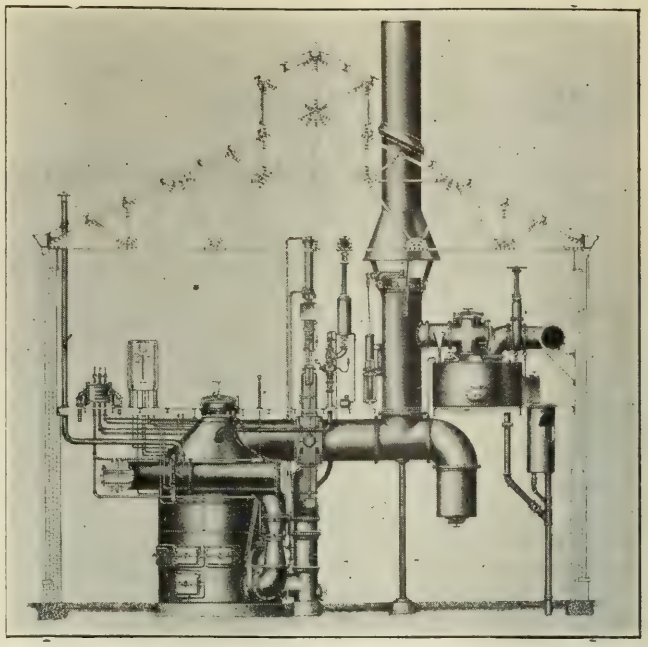
This surplus gas is distributed to nine cities and towns in the Empire territory as follows: Geneva, Auburn, Waterloo, Seneca Falls, Cayuga, Phelps, Newark, Palmyra and Lyons. The largest of these cities are Geneva and Auburn. The farthest point of delivery is Auburn, which is served by 26 miles of high-pressure main from Geneva.

The Auxiliary Blue-Gas Plant

The blue-gas plant was designed and erected by the U.G.I. Contracting Co., of Philadelphia, Pa. It consists of a generator building containing two 9-ft. diameter blue-gas generators and their necessary piping and accessories. These generators, of 7 ft. 2 in. inside diameter, have a grate area of 40.35 sq.ft. each. Their capacity is approximately 1,750,000 cu.ft. of gas each daily. The accessories include U.G.I. automatic control machines for the operation of the set; and two blowers, one motor and one steam turbine driven. There are also two steam-driven pressure pumps used in connection with the control machines. The motors, blowers and pumps are inclosed in a dustproof room on the ground floor. Included in this auxiliary plant is a relief holder of 100,000 cu.ft. capacity and a condenser equipped with sprays and grids—placed after the holder for cooling the gas.



SECTION THROUGH BLUE-GAS GENERATOR AND PIPING



ELEVATION OF BLUE-GAS PLANT

Steam for this blue-gas plant is generated in waste heat boilers and in boilers fired with coke breeze by Coxe stokers.

The handling equipment for feeding coke to the generators comprises a track hopper, a steel apron feeder and a belt conveyor. The belt conveyor has a travel of 200 ft. and is equipped with a 20-in. rubber-covered belt. This conveyor discharges into a storage bin and from there by chute to a charging car on the operating floor of the generator building.

Provision for future extension to this unit has been allowed in the layout. Space in the present building has been reserved for the installation of carburetors, by means of which the blue-gas could be enriched to the required heat and illuminating values for distribution to consumers, should such prove to be desirable.

Operating Mechanism and Methods

The automatic controls add greatly to the efficiency of the plant. When they are set and timed to run in a proper manner, the plant practically operates itself. All of the steam valves, air valves, stack valves, etc., are opened and closed automatically, being timed to the second. Much more efficient results are thus obtained than is generally possible by hand operation. The temperatures throughout the fuel bed are maintained within narrow limits, due to short cycles. The fuel bed is operated at its highest efficiency, producing a uniform quality of gas and a clinker which is easily and quickly removed.

The generator, a cylindrical steel vessel lined with insulating lagging and refractory brick, is provided with self-sealing doors, one at the top through which the fuel is fed, others giving access to the fire at the grate level, and one at the bottom. The air supply for blasting the coke to the proper temperature for gas generation enters the bottom of the generator, where it is controlled by a valve. The blast products, escaping from the top of the fire, pass through outlet connections controlled by special gas and stack valves, thence through the stack to the atmosphere. The installation is not equipped with waste heat boilers, although pro-

vision has been made so these may be installed in the future.

The hot gas outlets, provided with valves, are situated at top and bottom of the generator. When gas is being generated, it is taken off first at the top of the generator and then at the bottom. The operating mechanism which causes the reversal of these gas outlet valves also controls the steam supply and its regulation and the other parts of the accessory equipment, so that reversal for these is exactly synchronized with reversal of the gas.

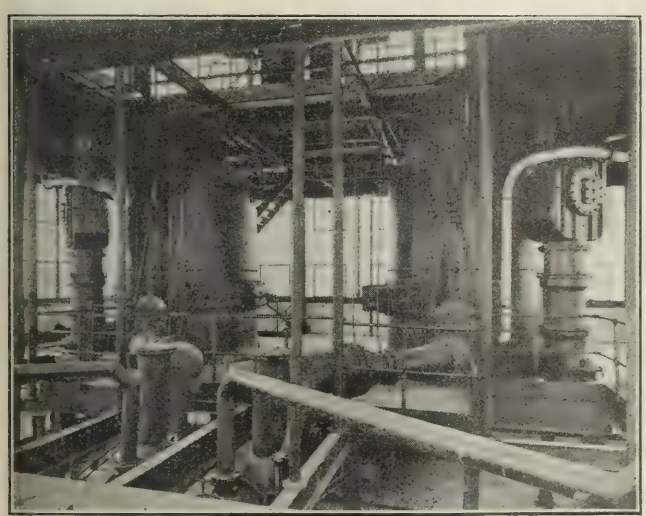
Operating Cycle for the Blue-Gas Plant

The process of making blue-gas consists of heating a bed of coal or coke to a predetermined sufficient degree of incandescence by an air blast through the firebed in the generator, and passing steam through the fuel thus preheated. After the fuel has been made properly incandescent, the steam is blown first up and then down through it until the temperature of the bed has been lowered somewhat. Then the steam is turned off and the fuel bed brought back to incandescence by the air blast.

The period of this cycle and the relative times of its various parts must be changed as required by changes in fuel or other conditions. The cycle found most economical at the Empire Gas & Electric Co. plant occupies 3½ minutes. This is divided into 25 per cent for blow period, 15 per cent for up-run steam, 45 per cent for down-run steam, and 15 per cent for up-run steam, making total of 100 per cent.

Operation of Blue-Gas Plant

The amount of air used varies with the fuel. The conditions are most favorable to gas making when the fuel bed is kept uniform. This plant has obtained good



SECOND FLOOR SHOWING THE TWO GENERATORS AND PIPING

results with an air blast of 10,000 cu.ft. per minute. The usual steam pressures are 90 lb. for up-run steam and 95 lb. for down-run steam.

It is the practice to clean the firebeds once each shift, or three times per 24-hour day. This cleaning occupies about 30 minutes, and can be easily accomplished by the coke handlers from the ovens without interfering with their other duties. The fuel is elevated by the same workers that elevate coal to the ovens. It does not require over 2 hours per day to accomplish the handling of sufficient coke to run the generators.

The product of the blue-gas plant is not at present accurately known, as it was not the former practice to meter the lean-gas used for heating and there is consequently no meter on the oven fuel-gas mains. It is expected, however, to install such a meter at an early date, and at that time the exact operating economy of the blue-gas can be figured.

Comparison of Blue-Gas and Lean Oven-Gas

The following is an average analysis of blue gas:

	Per Cent		Per Cent
Carbon monoxide	43.5	Oxygen	0.6
Hydrogen	47.3	Nitrogen	4.4
Methane	0.7		
Carbon dioxide	3.5	Total	100.0

The above analysis shows 91.5 per cent of combustibles and 8.5 per cent of inerts. Blue-gas of this analysis requires 2.3 volumes of air for complete

OPERATING FLOOR WITH AUTOMATIC CONTROLS AT RIGHT

combustion. This gas has a specific gravity of 0.559, a specific heat of 0.45 and a calculated flame temperature of 3,470 deg. F. Its calorific value is 302 B.t.u. per cu.ft.

A usual sample of the lean oven-gas would have an approximate analysis as follows:

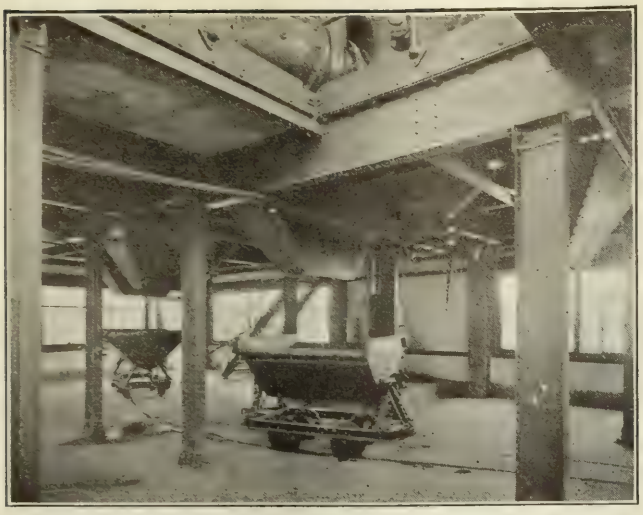
	Per Cent		Per Cent
Carbon dioxide	1.0	Hydrogen	51.9
Illuminants	1.4	Nitrogen	17.4
Oxygen	0.3		
Carbon monoxide	1.5	Total	100.0
Methane	26.5		

This is only a sample analysis of a lean-gas. This gas requires 4.25 volumes of air for complete combustion. Its flame temperature is 4,000 deg. F. Such a gas varies with conditions of carbonization and fluctuations in demand. For this reason it is not feasible to give any constants for lean-gas. The calorific value is found generally to vary between 380 and 450 B.t.u. per cu.ft.

Changing From Lean-Gas to Blue-Gas

One of the interesting points noted in the burning of blue-gas in the oven flues in comparison with lean-gas is that it is a much cleaner fuel. It is also noteworthy that greater operating efficiency is possible because the blue-gas is more constant in quality than the lean-gas.

The adoption of blue-gas as fuel at Empire did not necessitate any changes in burners or equipment on the ovens. The slip blanks which are inserted in the union of the 1¼-in. gas lines which feed the flues are



VIEW UNDER GENERATORS SHOWING CLEAN-OUT AND ASH CAR

disks with round holes varying in size from 8 mm. diameter for upper flues to 14 mm. diameter for lower flues. These serve to govern the amount of gas admitted to the combustion chambers.

It is interesting to note that the openings in these slip blanks were not enlarged or changed any way in changing to blue-gas fuel. The gas pressure in the fuel-gas line to the oven battery was increased by 3 cm. of kerosene, the amount of air admitted to the gas was reduced, and the stack draft reduced proportionately.

After these adjustments had been made no difficulty whatever was experienced and the heats were maintained without any trouble. There is no formation of soot or carbon in the flues when blue-gas is used, such as occurs when heating with lean oven-gas. This is a decided advantage. A slight disadvantage in the use of blue-gas is that sulphur collects in the burner pipes. This can, however, be readily disposed of by steaming out these pipes about twice a month; and is of no importance when the decided advantages obtained by using blue-gas are considered.

The writer wishes to acknowledge the courtesy of the U.G.I. Contracting Co. in supplying some of the photographs used in connection with this paper.

New Use for a Tiering Machine in the Chemical Industry

By Matthew William Potts

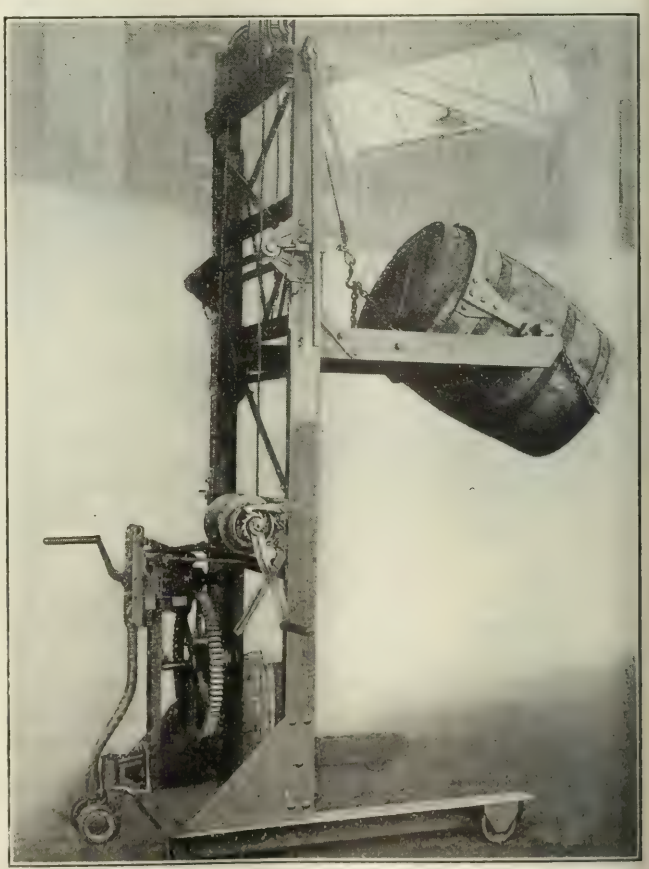
THE photograph herewith illustrates a new use for a tiering machine in the chemical plant. This machine was designed for and is being used by the Agar Provision Co., of Chicago, Ill.

This machine could be used in soap works, perfume and candy factories, packing houses—in fact any place where it is necessary to raise the container before dumping. Many times in passing through a chemical or dye plant, two to four men are seen struggling with a barrel, carboy or drum, trying to raise it so as to dump the contents in to a vat, tank or kettle. If the material being dumped is sticky, the job is made more difficult, as the men have to hold the container while another man scrapes out the contents.

The machine illustrated is portable and can be moved from place to place as easily as a truck. When the pulling or steering handle is in the position shown, the machine is resting on two feet—one at each corner—which grip the floor and hold the machine firmly in place. There is absolutely no danger of the machine slipping or tipping while the load is being dumped. When the steering handle is brought forward, the steering wheels engage the floor and the two feet are lifted about three-quarters of an inch. The machine can then be moved. When the handle is raised to the vertical position again, the machine is automatically locked to the floor and remains there rigidly fixed until the handle is again drawn forward.

Everything about this machine is standard construction with tiering machine manufacture except the tipping device, which is a special design. The tipping device consists of the machine platform arms, the container cradle or cradles and the small winch mounted on the machine uprights, including its cable and sheave.

The operation of the machine is simple and the machine and one man can do the work that with ordinary hand methods would require two or three men at least. When the machine platform is lowered, the steel cradle ring which holds the barrel rests upon the floor. The barrel is placed within the ring, the platform elevated slightly and two short chains are hooked over the chime of the barrel. The platform is then elevated to the height desired, the barrel being held in an upright position suspended within the ring. The cradle rests on two pivot points that are held in brackets or the platform arms. A chain is fastened to the cradle ring and in turn this chain is fastened to a cable which runs over a sheave and to the small winch mounted on the machine uprights. The barrel can be tipped to any angle or completely over and back, always under absolute control of the operator, by turning the hand crank of the small winch.



TIERING MACHINES FOR TIPPING BARRELS

Synopsis of Recent Chemical & Metallurgical Literature

Protection Against Cementation by Direct Application of Coating with a Brush

In the April, 1922, issue of *Revue de Métallurgie* Gailbourg and Ballay present the results of a rather extensive series of experiments upon local case-carburizing.

With the work of Guillet and Bernard as a starting point, they proceed upon the assumption that the best protection against cementation is to be found in a coating which carries copper to a considerable extent. The three methods mentioned for application of copper coatings are the electrolytic, by dropping in solutions of copper salts, and by means of the Schoop spray process. All these processes present some disadvantages in regard to cost, ease of operation, etc.

The authors present a new method of applying a copper coating by one direct application with a brush. At first they experimented with a coating produced by a mixture of resin varnish with copper dust. The results obtained with this coating were not successful and photomicrographs are shown to illustrate this. It is probable that the carbon in the varnish was responsible for part of the cementation.

Sodium silicate was next used as a carrier for the copper dust, equal portions, by weight, of the two being used. The objection to this combination lay in the cost of the copper, so a search was made for some inert material which might serve as a diluent for the copper. Such materials as kaolin, emery dust and iron oxide were used. Emery dust gave the best results. It was thought that possibly aluminum dust might be used in the place of copper, but the experiments wherein this was used indicated that its use was not warranted.

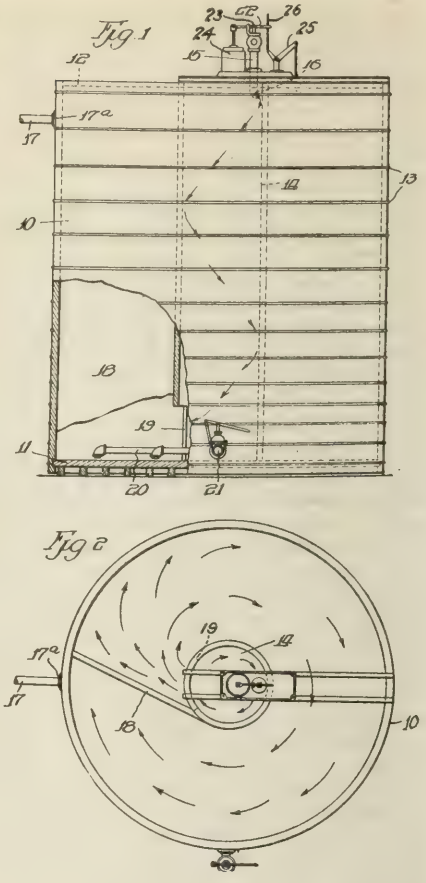
The Mixture Selected

The mixture which the authors finally selected as being the best bears the following proportions:

Copper powder.....2 parts by weight
Emery dust.....1 part by weight
Commercial sodium silicate in sufficient quantity to form a thick paste.

Before applying the coating, the pieces must be freed from all mineral oil, this being accomplished by placing them in an oven at 500 deg. C. A coating of from ½ to ¾ mm. is necessary to prevent cementation. From 15 minutes to 1 hour is required for the coating to dry. This time depends upon the temperature of the piece when the coating is applied.

The latter part of the article is devoted to a discussion of experiments designed to test the efficiency of copper coatings produced by dipping the articles in copper-bearing solutions.



The most successful solution used bears the following proportions:

$CuCl_2.2H_2O$ ..... 1 to 2 g.
HCl .....1c.c.
Butyl alcohol .....100 c.c.

The use of any of these solutions is apparently not unqualifiedly recommended by the authors, for they state in their conclusions that the coatings thus produced do not exhibit any marked superiority over electrolytic coatings.

No Provision for Removal

It is unfortunate that the authors do not describe a means for removal of the coating consisting of copper, emery powder and sodium silicate, as it is in that respect that most of the coatings of a similar nature have failed. The pure copper coatings do not interfere with any subsequent machining operations, but any coating which involves the use of sodium silicate would have to be removed before machining or grinding.

After a consideration of this work, the question arises as to whether or not the presence of copper is absolutely essential in a protective coating of this nature. Experiments carried out at the University of Michigan[1] have seemed to demonstrate that copper is not essential, good protection being secured by the admixture of asbestos and alumina with sodium silicate.

[1]See "Selective Case-Carburizing," by W. P. Wood and O. W. McMullan, *Chem. & Met. Eng.*, vol. 26, p. 1077 (June 7, 1922).

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Settling Tank.—Walter H. Green has designed the settling tank shown in the accompanying drawing for the purpose of causing the flow to pass through the maximum travel while within the tank, thus achieving maximum settling with minimum space requirements. As will be noticed from the drawing, the inlet and outlet are both at the top of the tank, and by means of a series of baffles the fluid from which the solid matter is to settle is caused to make the maximum amount of travel while within the tank which is available if the precipitated matter is to be removed from the bottom of the tank. (1,417,516; Walter H. Green, assignor to International Filter Co., May 30, 1922.)

Fume Control Device.—In heating and treating industrial materials, especially when of a chemical nature, there is liability of the evolution of fumes possessing flammable or explosive properties. The device covered in this patent is for the purpose of governing these fumes at the time and place of their inception by automatic and simple means which will not interfere with the apparatus with which it is employed. The essential feature of this device is a means for disposing of the fumes in a harmless way should ignition or explosion occur. This is accomplished by having the fumes led directly from the place of generation to a chamber having two exits—a normal exit and an emergency exit. When the normal exit is in use, the emergency is closed, being held so by a fusible link. Should this link melt, due to flame or explosion, the normal exit is closed and the fumes are led through the emergency exit to a place where they can do no damage. (1,414,722; Vern K. Boynton, assignor to Perry & Webster, Inc., May 2, 1922.)

Blasting Dynamite.—Blasting dynamite with improved stability and high velocity detonating properties is claimed by Wendell R. Swint in a specification covering the use of smokeless powder and cordite with the usual sodium nitrate and chalk but containing 3 to 15 per cent water.

The smokeless powder and the cordite are ground separately with water, the excess water being removed by centrifuging. The ground smokeless should then contain about 15 per cent water and the cordite 10 per cent water. In this condition they are mixed in the proportion of 28 parts smokeless, 40 parts cordite, 31 parts sodium nitrate and 1 part chalk. (1,411,674; Wendell R. Swint, assignor to E. I. du Pont de Nemours & Co., Apr. 4, 1922.)

Book Reviews

THE MANHOOD OF HUMANITY: THE SCIENCE AND ART OF HUMAN ENGINEERING. By *Alfred Korzybski.* New York: E. P. Dutton & Co., 1921. 208 pp. (Appendices, III.)

EDITOR'S NOTE—The interest displayed among our readers in this book has prompted one of our friends to call our attention to a review of it by Dr. Frankwood E. Williams in *Mental Hygiene.* Dr. Williams is as prominent in his field of endeavor as are the leading chemical and metallurgical engineers in their respective fields. The latter will undoubtedly be deeply interested in the reflections of a physician on the ideas and habits of thought of engineers.

This book has been so much praised—it has been called "epoch making"—that, having finished it and found little of value in it, one wonders if possibly the point of it all has been missed. But on looking through it a second time, it does not seem that the main points have been lost. There are, apparently, three of these, and as they are mentioned in each chapter, not once but several times to the verge of tedium—in fact, the author never seems to get at the real problems of the "science and art of human engineering" because he is so occupied in belaboring his three points—it is impossible to miss them. These points are: (1) Man is not just an animal. (2) Neither is he a combination or union of animal with something supernatural. (3) Man is literally a part of nature and of a different "dimension" than animals. By this latter the author means that man is distinguished by "time-binding qualities"—human beings are "time-binders." (Plants are "chemistry-binders" and animals "space-binders," according to the author.)

The expression "time-binder" is the best contribution the author makes. While there would seem to be nothing new in the conception of "time-binding," the expression itself is a happy one, so rich in imagination that one is surprised to find it in a book on "engineering," praised by engineers and mathematicians, until one remembers that genuine imagination lies rather with the engineer and the mathematician than with the poet and philosopher, as is so commonly supposed.

Count Korzybski is very much in earnest about these three points, and while it does not seem possible that an intelligent person would take serious issue with any one of them, he would seem to feel that the intellectual world is armed to the teeth against them. We have, therefore, not so much a book on the "science and art of human engineering" as a book devoted to proving that man is not just an animal, is not part animal and part supernatural (in fact, is not supernatural at all) and is more than animal because he has a fairly long memory (time-binding quality) and can use it; with a promise that more may be said later, but that not until we have grasped these points will we sufficiently understand human nature to consider undertaking human engineering. One gets the impression, somehow, that the author has been a very busy man in fields quite apart from human engineering—he is a military man, one gathers—but that, as an avocation perhaps, he has let his mind ruminate on some of these problems until he has come to the same conclusion as a good many others—that the greatest study of man is man; only Korzybski stops here while others have pushed from this point and have tried to understand man. It is quite evident that while Count Korzybski has been thinking on these problems he has not been studying them in the sense of ascertaining what data already exist on the subject of human engineering. It is a bit as if an engineer came forward, year 1922, with a book announcing that there is no reason why a heavier-than-air machine should not fly; that it is important that we develop flying machines, as they would have a use both commercial and military; and that he believes he is on the track of principles that will make flying possible—evidently not aware that the Wright brothers flew 18 years ago and that there has been considerable successful experimentation and development of airplanes since.

The general practitioner of medicine, and the layman, frequently complain that the psychiatrist uses a language—a "jargon" they call it when something eludes them—that they cannot understand. They seem to feel that something is being kept from them, that somehow it should all be made a little easier for them. They are not altogether wrong in this, although they forget that every profession, even every occupation or trade, has its own specialized vocabulary; that the reasons for this vocabulary are definite and important and even apparent, if one stops to think, and that one cannot expect to understand technical matters of law, or architecture, or bookkeeping, or farming, or the teaching of English, without first becoming acquainted with some of the special terms commonly used. One can imagine an engineer, for example, frowning at the technical terms in Paton's "Human Behavior"—why does the man hide behind these words? It is interesting to see, therefore, how simply things can be stated for the engineer. Here, for example, is Germany mobilized:

" . . . a state is the governing center of an accumulation of human beings—of time-binding powers—increasing exponential functions of time. These powers, though the same in kind, differ in degree and in respect of individuality. If they are to be united so as to constitute a whole, they must be given a common aim; they must, so to speak, be reduced to a common base; if they be respectively X^m, Y^n, Z^p, and so on, we cannot unite them and compute the whole by adding the exponents; but if we give them a common base—a common aim or purpose—then we can readily represent the magnitudes of the whole constituted by them; if we take X to be their common aim or base, then, if Y equals aX, Z equals bX, and so on, we shall have:

$$X^m Y^n Z^p \ldots = X^m a^n X^n b^p X^p \ldots = (a^n b^p \ldots)\, X^{m+n+p\ldots}$$

"The last expression, where the parenthetical coefficient is the product of individualities, serves to represent the united powers of all in terms of X, the common base, purpose or aim."

In addition to the contribution of the terms "time-binder," Count Korzybski's book will probably be useful in another way. If the book arouses interest in the science and art of human engineering on the part of the president of the International Rotary Club, the vice-president of the Association of Mechanical Engineers, eminent consulting engineers and the professors of mathematics at Columbia and elsewhere (all quoted as praising it), it will be the most useful book on the subject yet printed. And if, their interest stimulated, these business men, engineers and mathematicians wish to continue their studies, they might begin with—a number of books come to mind, but, for example, White's Foundations of Psychiatry.

FRANKWOOD E. WILLIAMS.
The National Committee for for Mental Hygiene.

MANUFACTURING COSTS AND ACCOUNTS. By *A. Hamilton Church,* consulting industrial engineer. First Edition. New York: McGraw-Hill Book Co., Inc. 450 pp. Price $6.

The author has aimed in this book to present a simple view of the general structure of cost accounts and to introduce gradually to the student the underlying principles on which manufacturing accounting of all kinds must rest. The relation of the cost accountant's work to the general accounts is clearly shown and to the general accountant the peculiar value of detail to the cost man has been emphasized.

The book is divided into three parts. Part I presents the general outline of manufacturing accounts; Part II covers cost accounting; Part III shows the factory reports and returns.

The mechanism of accounting is explained in detail with the aid of symbols and diagrams. By these diagrams, quantities and values are shown flowing from the purchase and cash journals to the ledger accounts and from these through the burden and manufacturing journals to the burden and manufacturing accounts, the burden account being later transferred to the manufacturing account. The methods of connecting expenditure incurred in manu-

facturing with individual quantities of product are presented fully. The selection of an appropriate cost system is shown to be governed by three main conditions:

1. The method in which direct labor and expense are applied to the product.
2. The unit quantity of product selected for costing.
3. The degree of detail required in the costing of this unit quantity.

The major portion of the book is devoted to the explanation of the three methods (A, B and C) of charging expense to the product after the amount of burden applicable to each department has been determined by taking into account the amount of equipment, internal expense and the proration of the expense departments on some basis that implies measuring the cost of service as each department has received it.

In Method A the expense is merged and averaged with Direct Labor, and charged to unit quantity of production on a time basis, the material being charged direct to individual orders. This method of costing requires that there be no substantial difference in wage rates between operatives engaged in any one department or performing any one operation and that all product has the same and entire series of operations. Consequently this method of connecting labor and expense with output is limited to homogeneous products.

Method B averages Expense and charges it to Orders in proportion to direct labor or labor hours. Labor and material are charged direct to the orders. Although the most widespread of all methods of costing, it has the disadvantage of being more or less incorrect due to the fact that it is seldom true that all machines used in production are of the same cost, occupy the same space, take the same power or entail the same supervision. If expense is very small compared with labor and material, this approximate method will cause no great harm, but on account of its "simplicity" is unfortunately applied in shops where expense may be many times the direct wages. Piecework, premium or bonus wage systems may be used. For hand industries this method is quite satisfactory.

Method C is the "machine hour rate" in which normal expense is divided into factors which are allocated among different machines on a basis determined by the contribution of each factor to the running of each machine. The total found allocated against each machine divided by the number of working hours in the period for which the calculation has been made gives an hourly machine rate. By this method the cost of idle machines can be ascertained and investigations made to determine cause and apply the correct remedy. This cost of idle machines can be written off to Profit and Loss or applied as a supplementary rate to Production Orders, especially if the industry is in a position to recover this wasted capacity in the selling price of its products. In either case the amount is a barometer of the cost of non-production caused by conditions of trade or more often by poor management. The author, who was among the first to introduce the "machine hour" method of distributing expense, gives detailed methods of determining the correct production factors and hourly rates.

The author has devoted several chapters to purchasing and stores, time and pay, production and standing orders, and the preparation of cost sheets. Sample forms have been profusely used to make the subjects clear to the reader. The chapter on standing orders shows a very complete system for collecting expense in intelligible forms.

Under "Factory Reports and Returns" the author emphasizes the fact that the cost system to be satisfactory must furnish an aid to efficient management and production as well as obtain figures and statistics as to the financial condition of the business. The shop wants its data "red hot," while the higher officials desire information more general in type but with clearer and more systematic grouping and presentation. The reports for foremen, superintendents, executives and proprietors are clearly indicated and their derivation from various parts of the cost system shown.

With the fundamental information contained in this book the student should have no difficulty in applying cost sense to the particular problems that may be met.

WILLIAM B. TODD.

CANE SUGAR. By *Noel Deerr*. Second (Revised and Enlarged) Edition. London: Norman Rodger. New York: D. Van Nostrand Co. 644 pp., 30 plates (12 colored), and 360 illustrations in the text. 1921. Price $10.

A standard reference book! Think for a minute what this means. Then consider the sugar chemist, engineer and plantation manager—nobody realizes better than these men themselves when far away from the city library and in the midst of the sugar-making campaign how much they need an authoritative, complete and up-to-date reference book covering every phase of the sugar industry. Such a book is "Cane Sugar," by Noel Deerr.

When the Sugar Chemists and Technologists tendered Noel Deerr a farewell banquet in New York on Sept. 30, 1920, Dr. C. A. Browne as toastmaster remarked that Mr. Deerr's chemical and technological attainments placed him foremost among the cane sugar experts of the day, and also stated that with his departure America was losing the man who had the greatest bibliographical knowledge of the works and publications on sugar in the libraries of her great cities. Regret was expressed that Mr. Deerr's departure prevented the realization of his plan to compile a much-needed bibliography of the works and references pertaining to the botany, history, agriculture, chemistry and technology of sugar and the sugar cane.

If indeed regret must be expressed that the author's bibliographical work lacks somewhat of being fully complete, the reviewer feels that this loss has been compensated in great degree by the very excellent summations of the literature and the inclusion of the most important references. Each chapter of this book is appended by a list of references to the literature and patents cited which adds greatly to the value of the work as a whole.

In addition to the lists of journal articles and patents to which reference is made in the text, the edition is appended by a very complete bibliography, the various works being arranged for convenience under the following headings: Older Monographs; Works on Travel, Histories, etc.; Encyclopædias and Dictionaries; Works Dealing With History and Commerce; Works Dealing With the Agriculture of the Cane; Books Dealing With Sugar Manufacture; Works on Analysis and Chemical Control; Works Specialized on Steam and Engineering; Books Dealing With the Chemistry of the Sugars; Books Dealing With Pests and Diseases; Works on Filtration; Works on Rum; Bibliographies; Various Unclassified Works.

An interesting historical conspectus traces the progress of the industry from 327 B.C. to the beginning of the Great War in 1914.

The author has arranged the chapters of this textbook into three parts. Part I deals with the agriculture of the sugar cane, Part II with the manufacture of cane sugar and Part III with the analysis of sugar-house products.

In Part I are included chapters on the composition of the sugar cane, description of cane varieties, classification and discussion of soils, cultivation, manuring, diseases and pests, and harvesting.

The second part begins by discussing the extraction of the juice by mills, and traces the process of manufacture to sugar in the bag and disposal of molasses and bagasse. The chapters in this section are entitled Extraction of the Juice by Mills; Diffusion Process; Action of Heat, Alkalis and Acids on Sugar and Cane Juices; Defecation of Cane Juice; Carbonation Processes; Sulphitation; Filtration; Evaporation; Sugar Boiling and Crystallization-in-Motion; Separation of the Crystals; Molasses; and Bagasse as Fuel.

In the third part the author describes the polarimeter, methods for determining cane sugar and reducing sugars, the assay of sugar-house products, and the chemical control of the factory.

An additional chapter is devoted to fermentation, with special reference to the sugar-house and to the fermentation of molasses.

The value of the book as a whole may be attributed to the fact that the subject matter is discussed from both theoretical and practical standpoints, by a man "who has his head up and both feet on the ground." An experience of 25 years is back of it.

Although much of the data is pre-

sented in chronological order tracing technical progress, the various merits and imperfections in types of equipment and advantages and disadvantages of different practices are discussed in such a way that the reader may easily follow the advances in the industry and thereby acquire a sounder and more rational idea of the "reason why" of present practice. At the same time, however, questionable present-day practices which must be further investigated before universal acceptance are dispassionately treated of from the open-minded viewpoint.

As a text and reference book "Cane Sugar" surely calls for no adverse criticism. It is all good. Certain subjects to be sure are treated of more comprehensively elsewhere, but in covering the field so broadly in one volume the author has done well to condense and summarize. To single out minor points for criticism would be superficial in the extreme and would detract none at all from the value of the book to those for whom the author has written it. C. F. WALTON.

AN OUTLINE OF QUALITATIVE ANALYSIS OF INORGANIC SUBSTANCES, INCLUDING THE RARE ELEMENTS. By *Horace G. Byers.* New York: D. Van Nostrand Co. 227 pp. Price, $2.

The book is planned to serve as a guide in courses in which qualitative analysis is presented as a laboratory course to accompany lectures in the general chemistry of the metals. It represents the result of over 20 years' experience in teaching general chemistry and qualitative analysis. Part I "is essentially a syllabus of lectures" upon the procedure and theories of qualitative analysis. In the early pages of this part the purposes, ideals and necessary precautions are set forth in a clear and inviting fashion. It is evident that at the start the author has had in mind the perplexities of the beginner. But one can scarcely help wondering if he has not forgotten the limitations of his students when in discussing the theories of solution he attempts to summarize in brief sentences the divergent views of van't Hoff, Jones, Werner and Kahlenberg, and then harmonize them all in a theory of his own for which he says "he is not able to secure adequate experimental evidence." Would it not be better to select the best of the current theories for the beginner and leave the discussion of the merits and weaknesses of conflicting theories to an advanced class in analytical chemistry or to a graduate seminar? Many teachers will prefer, also, to leave their qualitative students in ignorance of the Lewis-Langmuir theory rather than to be content with the statement that "this theory is not such as may be summarized simply and the student is referred to the original articles. . . . "

Anion analysis precedes the analysis of the metallic ions because in the opinion of the author "there seems to be no logical reason against this order and some very good reasons for it." Not all teachers will agree with him on this point. The methods of identification are "conventional," and the presentation is admirably made. The section on systematic analysis is clear and so well arranged that a student should be quite independent. In a few places he will need help, as for instance when he attempts to get an alloy containing tin into solution with boiling concentrated nitric acid (p. 129), or when he attempts to remove phosphates in the absence of iron (Table VII, p. 150).

The most characteristic portion of the book is Part V, which is devoted to the detection of the rare elements. No attempt is made "to provide a comprehensive treatment of these elements, but rather an outline of the procedures by means of which their presence may be recognized and the means of identification; at least so far as to enable the student to know when he should consult larger texts." The general plan of procedure used in the analysis of the common elements is followed. The presence of rare elements produces certain peculiarities in the preliminary examination, the interpretation of which is given in tabular form. The individual rare elements are grouped according to the usual five metallic groups and characteristic reactions are given for most of the elements. The analysis of each group follows the general scheme, but there are few attempts made to correlate the analysis of the rare elements with that of the more common ones. Frequent references are made to larger works where more detailed information is available.

The appendix contains much useful information for both teacher and student. A more extended table of solubilities would have been welcomed by many. Only a few typographical errors are observable, such as the production of $SnCl_2$ by action of HCl on SnS_2 (Table V, p. 148).

The book shows clearly the wide experience of its author. It will be very useful, especially to the rapidly increasing number of chemists who desire accurate information concerning the qualitative analysis of the less common elements. B. S. HOPKINS.

REVIEW OF PAPERS ON ELECTRODEPOSITION AND ELECTROPLATING. Transactions of the Faraday Society, vol. 16, Part 3, July 1, 1921.

The several papers presented in this book are of much interest and they, along with the discussion, give the opportunity of obtaining a "close-up" of the electroplating industry in England. As a whole the papers are excellent. There is evidence of a great deal of hard, conscientious work by each author. The amount of data given is proof of the desire to give the details that are so essential to a clear conception of the author's opinions.

The discussion is remarkably frank and the reviewer is left very little to do, so thoroughly has each paper been criticized. The papers should be read by every one interested in electrodeposition of metals. While there are points upon which entire agreement will not be possible, it must be admitted that in general they are the best that has so far been published in any one volume. The progress of electroplating seems to have been greater in this country than in England. The commercial application for ornament and protection of metals is done on a larger scale and more study has been given to details.

Dr. F. C. Thompson at the beginning of the discussion very truly states: "I have only one other thing that I should like to say, and that is that in some respects the present meeting is undoubtedly an historical one. In America and on the Continent a great deal more attention appears to have been paid to the problem than has been the case in this country, and the Faraday Society, in bringing together the large number of papers which have been presented at this meeting, has done something which has never before been attempted, to my knowledge, in this country."

We say that such meetings bring all interested in electrodeposition closer together. Let there be more of them. Better still, why not have a joint meeting of the Faraday Society and the American Electrochemical Society and have a session devoted to the electrodeposition of metals?

GEORGE B. HOGABOOM.

DYES CLASSIFIED BY INTERMEDIATES. By *R. Norris Shreve,* in collaboration with *Warren N. Watson* and *A. R. Willis,* Chemists, U. S. Tariff Commission. New York: Chem. Catalog Co., Inc. 8vo, 631 pp. Price, $10.

In the opinion of the reviewer, the authors have rendered a very valuable service to the cause of American dye chemistry in the compilation of this classification, for after all the intermediate is the more important factor in a modern dye plant, since from it not one but many dyes may be manufactured, and nowhere is this more clearly or more compactly exhibited than in the publication under review.

The plan of the work is set forth in the Introduction (pp. 7-15), which includes also a brief description of the system of nomenclature used by *Chemical Abstracts* and its relation to other systems in vogue today.

Part I, Intermediates and Dye Tables (pp. 17-581), constitutes the body of the book, and is composed mainly of an alphabetical list of intermediates. The various names by which these different intermediates are known appear each in their appropriate alphabetical place, but the dye tables and other data are given under but one of these synonyms, all the others being referred to this principal name. In some cases, the *Chemical Abstracts* designation is given the preference, in others

the common trade term is chosen as principal name. After each preferred title appear first its synonyms, then the constitution and molecular formulas of the compound, its molecular weight, a condensed outline of its method of preparation, a citation of the pages in standard reference works where further information can be found, and a tabular statement of dyes produced from it giving Schultz number of the dye, its ordinary trade name and class (structural), statistics of importation and manufacture for the United States, other intermediates employed with it for the preparation of the dyes listed, pertinent notes, and dye application class. Under aniline, for example, appear 104 different dyes, under benzidine 88, under H acid 41, etc. Each dye appears under each of its intermediates.

The list of intermediates and dyes is followed by a Formula Index of the 487 intermediates recorded, the molecular formulas being arranged as in the formula indexes of *Chemical Abstracts*, and each formula being followed by the principal name of the intermediate and a reference to the page whereon it is described. With this Index and the *Chemical Abstracts* name given after each intermediate, reference to the volumes and the index of *Chemical Abstracts* is easy.

In addition, the authors have given a very extensive Glossary of Dye Names (about 5,000), wherein they have endeavored to record the trade names of the better known commercial brands, noting the name of the manufacturer and appending the correct Schultz number wherever possible. This glossary is based largely upon the list given in the index of Norton's "Artificial Dyestuffs Used in the United States."

The book concludes with a Page Index of Schultz Numbers for Dyes, so that knowing the Schultz number the reader can locate at once the page or pages whereon the dye will be found tabulated.

Although in the dyes listed under each intermediate but one of its various names is assigned to each individual dye, there will be no difficulty in locating it through the use of the glossary and Schultz index mentioned. No worker in this field, be he manufacturer, investigator or teacher, can afford to be without this volume, and he should be grateful to those whose labor has made this mine of useful information available in such compact and serviceable form. Were it practicable, in future editions, to add also data showing the uses to which these same intermediates are put in the manufacture of drugs, perfumes, photographic chemicals, explosives, toxic gases, incendiaries, signal flares, synthetic plastics, synthetic tannins, etc., those responsible for framing legislation which will protect adequately the dye industry could see at a glance its widespread and far-reaching ramifications and the vital part it plays in the life of the individual citizen and of the state in our present civilization.

The book is clearly printed upon good paper, with remarkably few typographical errors for so difficult a composition, and makes a most attractive volume in its dark red buckram binding.

MARSTON TAYLOR BOGERT.

THE ELECTRIC FURNACE. By *J. N. Pring*, M.B.E., D.Sc. 485 pages, illustrated. New York: Longmans, Green & Co. Price $10.50.

A really satisfactory text book dealing with the electric furnace is a publication that is much to be desired. The electric furnace has now become a commercial apparatus that is applicable to a great variety of uses, while at the same time it is a most valuable tool in many fields of experimental work. It is not easy, however, to find the man who is qualified to treat the subject as it deserves. It would obviously be impossible to find anyone who had experience with all the electric furnaces that are used or even with a considerable percentage of them; but the author of a text book should at least have had intimate experience with some of the varieties of experimental furnaces and with some representative examples of commercial furnaces used for the different purposes where the electric furnace is the best or the only suitable apparatus. Unless he has this first hand knowledge of the subject, his text book, compiled from the large and highly diversified literature on the subject, is apt to be unsatisfactory to the reader who himself has a practical knowledge of some branch of electrothermics, and actually misleading for the reader who is altogether unfamiliar with electric furnaces.

The task that Mr. Pring has set himself in his book appears to be set forth in this paragraph from his preface:

"The most noteworthy branches of electrochemical and electrometallurgical industry have, within the last decade, been described in a number of publications. Nevertheless, the present rapid progress of these enterprises demands a frequent revision and extension of the literature of this subject as contained in the textbooks. No apology is needed therefore for the attempt, at this stage, to introduce an additional contribution to the general technical discussion of the position and prospects of high-temperature industrial chemistry."

One of the most important uses of the electric furnace is in the production of ferro-alloys, and yet the space devoted to it in this work is only ten pages while eighty pages are devoted to the electric steel furnace. Now, important as is the use of the electric furnace in the manufacture of steel, there appears to be a lack of balance in a text book forming one in a series of "Monographs on Industrial Chemistry" which devotes eight times as much space to that subject as to the production of the numerous ferro-alloys, products of the electric furnace and of the electric furnace alone. No doubt the excuse for this is to be found in the great quantity of advertising matter, exploiting various kinds of electric steel furnaces, with which we are flooded as compared with the shrinking modesty displayed by those interested in selling ferrous and non-ferrous alloys.

As to the revision of the current text books, it is regretable that this has not been more thorough, because the inclusion of obsolete or incorrect information not only crowds out useful matter but is misleading to the uninitiated. For example, it is unfortunate that data, quoted from Borchers, dealing with the permissable current density in carbon electrodes, should appear on page 391, from which it seems that 64 amperes per square inch may be used in a rod 2 in. in diameter, but only 10.7 amperes per square inch in a rod 16 in. in diameter; therefore, "it is usually found preferable to build up the larger electrodes from a bundle of smaller rods."

It is because of such lapses as this and the lack of balance in the space devoted to various uses of the electric furnaces that one is led to the conclusion that the author's practical experience with furnaces is not wide enough to qualify him to write that ideal text book referred to above. In spite of these faults, however, it may be said that Mr. Pring has been successful in making "an additional contribution" to the text books dealing with electric furnaces that will be of use to those interested in the "general technical discussions of the position and prospects of high-temperature industrial chemistry."

After a brief historical sketch the author has an interesting section on laboratory furnaces followed by two good sections on current supply and transformers. In the latter chapter he does not describe the induction regulator, a valuable apparatus where uniform variation in voltage is required. In section 10 the electric smelting of iron ores is treated. In the description of the Swedish work on this problem the relation of it to Dr. Heroult's experiments at Sault Ste. Marie for the Canadian Government is not brought out. It is a pity that the work done with synthetic pig iron during the war is not discussed. In treating of the electric metallurgy of zinc it is a little difficult to understand why space should be devoted to hydrometallurgical methods, as the book professes to treat only of electric furnaces. Section 22, on the design of electrode terminals, is rather weak so far as practice in this country is concerned. The inclusion of a section on waterpower developments and steampower stations is a good idea, and the bibliography which appears as Appendix B is decidedly useful.

Chemical Foundation Plans Fight to Finish Against Return of Patent Rights

General Uncertainty Prevails as to Real Signficance of Move, While Speculations of Political Play and German Propaganda Are Rife

IF THE Alien Property Custodian secures the return of the patents and other rights purchased by the Chemical Foundation, it will be only after the Foundation has exhausted every legal recourse in its effort to retain them. The position of the Foundation is that the President must have been misled. It is believed, however, that the detailed study of the whole transaction, which will have to be made in connection with the court actions which will be taken, will reveal to the satisfaction of the administration as well as to others interested in the establishment of a domestic chemical industry that no organization could have more altruistic and patriotic objectives.

There is no tendency to charge ulterior motives to any of the administration officials involved. It is very generally believed that their action is based on the very plausible case which has been built up by those interested. The opinion is expressed that the Attorney General, smarting under the attacks which have been made on him, rather welcomes any action which may serve as a smoke screen and divert from him some of the objectionable attention which he has been receiving.

Bitter Fight Expected

The fight over the Chemical Foundation purchases promises to be a particularly bitter one. Some of the friends of the Foundation are condemning the administration's action in a most unqualified way and declare that the special representatives of the German chemical industry must be fast workers as they have been in the country for only four weeks. For the most part, however, those particularly interested in the building up of a domestic chemical industry are making no charges of untoward influencing of officials by German interests. They point out that political expediency hardly could have prompted the move since it is certain to be unpopular to restore to former enemy aliens property which will deprive the American people of great benefits. Perhaps the best example of a benefit which the public is receiving is shown in the case of the salvarsan patent. Whereas the price per dose was maintained at $4.50 as long as the patent was in German hands, a more uniform product is now available for $1.50 per dose. The Foundation has applied this policy to all of the patents under its control.

While it has been known for some months that an informal investigation of the Chemical Foundation has been in progress, at no time has the Foundation been called upon for information of any character. It is for this reason that many conclude that the Alien Property Custodian has been informed of one side of the case only.

Attack on Foundation Late

In connection with the demand for the return of the patents held by the Chemical Foundation, it will be recalled that this organization was not formed until after every effort had been made to find a way whereby these patents could be turned over to a governmental agency. Mr. Garvan in testimony before the Ways and Means Committee in 1919 and before the Senate Finance Committee in 1920 expressed willingness to turn the patents over to any governmental agency and urged the Committees to make suggestions as to how that could be done. No suggestion has been forthcoming from either Committee.

Harding Letter Demands Return of Patents

The text of President Harding's letter to Thomas W. Miller, Alien Property Custodian, ordering the return of the patents transferred to the Chemical Foundation under the previous administration follows:

My dear Colonel Miller:

My attention has been called by the Department of Justice to the fact that a corporation known as the Chemical Foundation has brought suit against the Treasurer of the United States and certain licensees of the Federal Trade Commission for an accounting alleged to be due the said Chemical Foundation on royalties due it for the use of certain patents originally seized under the authority of the Alien Property Custodian and sold to the Chemical Foundation by the Custodian during the previous administration. On the face of such an action it became so apparent to me that an inquiry should be made, that I asked for a report by the Department of Justice on the sale of this enemy property to the Chemical Foundation. It appears that the sale was made at so nearly a nominal sum that there is reason to believe that this government has not faithfully observed the trust which was implied in the seizure of this property. The circumstances relating to the entire transaction are of such a character that full investigation becomes a public duty. Moreover, I feel that your office is obligated to maintain the sacred character of the trust to which the Alien Property Custodian is committed by the law.

You are therefore directed to forthwith proceed as follows:

1. Make written demand upon the Chemical Foundation, Inc., in form to be approved by the Attorney General, to immediately return, transfer and assign to the Alien Property Custodian, all patents, trademarks, copyrights, contracts, applications or other properties or rights transferred to it by the Alien Property Custodian as aforesaid, and to account to you for any and all rents, profits, license fees, or other proceeds thereof realized by said Chemical Foundation, Inc., from said properties, or rights or any of them, from the date of transfer thereof to the Chemical Foundation, Inc., to the date of restitution.

2. Take any other action which may be advised or approved by the Attorney General, by suit or otherwise, to fully and in every respect protect the rights or interests of the United States and any other person or corporation interested therein, in and to the properties and rights aforesaid, and any proceeds, income or profits therefrom in the hands of the Chemical Foundation, Inc., or its officers, agents or employees.

In carrying out these instructions you will act upon the advice of the Attorney General.

Very truly yours,

WARREN G. HARDING.

Government Institutes Criminal Proceedings

Criminal proceedings against the Chemical Foundation were begun on Saturday by Attorney General Daugherty and a subpoena was served on Francis P. Garvan, President of the Foundation, calling for immediate production of all of the Foundation's books and papers before a Federal Grand jury in Washington, D. C. The decision to conduct a criminal investigation instead of a civil suit was a complete surprise to Mr. Garvan, who was at a loss to account for this move on the part of the government.

Garvan Charges German Intrigue in Demand on Chemical Foundation

Rescission of Sale of Chemical Patents to Chemical Foundation Is Attributed to the Scheming of German Cartel's Representatives

DEFIANCE to the government's demand for the return of the 4,700 German patents held by the Chemical Foundation, Inc., and a strong insistance that this action is the result of German intrigue are the outstanding notes in the several statements issued by the Foundation's president, Francis P. Garvan. This official, on receipt of the first news of the President's letter declared that "this action was taken without any notice to the American organic chemical industry or to the Chemical Foundation or any of its officers or to, in fact, anyone equipped to speak for this essential American industry in peace and war. It has been begun I am informed after a full hearing by the representatives of the German Cartel, the German Dye Trust and the German Government without any American interest being given an opportunity to be heard in reply."

Mr. Garvan maintained that it was these "powerful friends at court" who had aided in the scheme to regain control of the American organic chemical industry, which had been lost to the Germans during the war. The return of these patents was a necessary step in the German program for the following reasons:

> They know that the upbuilding of German industry to the point already visioned by the industrious and ambitious German mind, is, if not impossible, rendered extremely difficult by American possession of the patents of this basic industry.
>
> They know that unless they can strangle American competition now the American organic chemical industry soon will be too solidly established to be affected by German competition—under any reasonable form of protection.
>
> "They know that if the American organic chemical industry can be wrenched loose from the Chemical Foundation it can be attacked piecemeal and destroyed, the patents, of course, reverting to their former German owners, spies and enemy aliens."

German Lawyers in Washington

The actual workings of this intrigue were discussed in a statement which Mr. Garvan made to the press on July 7, in which he outlined two significant developments.

> 1. Within about three weeks a commission, consisting of three German lawyers, Rudolph Oppenheim, Hans Wagner and Karl Holderman, representing the German Cartel, which in turn consists of all the organic chemical industry of Germany, arrived in this country to perfect plans for the recovery by Germany of their control in America of the organic chemical industry. On Saturday, June 24, a conference was held at the office of O'Gorman, Battle, Vandiver & Levy, of 37 Wall St., at which were present Mr. Vandiver and Mr. Levy, representing Herman A. Metz, the leading German importer and agent of the "I. G.," and several other lawyers representing the German Embassy and other German interests. It was there decided that a direct action by Germany or by the Cartel to upset the sale to the Foundation would be inexpedient, but that the most promising form of procedure would be to attempt to induce the United States Government to bring the action and to offer to the Government all possible German assistance. Accordingly, a committee was appointed consisting of Messrs. Oppenheim and Wagner, Vandiver and Levy to go to Washington and consult with the Department of Justice.
>
> 2. On Tuesday, June 7, this committee visited the Attorney General's office and there placed before his assistants the German proposition and offered German assistance. Prior to that time neither the Chemical Foundation nor anyone in any way representing them nor anyone representing any part of the American organic chemical industry had been asked any question in reference to the sale and subsequent to the visit of the German representatives no request or opportunity was given to any American interests to answer the German representatives before the announcement of the intended demand was made.

Other Patents Involved

The demand on the Chemical Foundation naturally raises the question as to whether the case will become a precedent governing other patents sold by the government. In answer to this question, Mr. Garvan declared that the demand would involve: "First, the sale of all wireless patents and plans to the United States government 'for the nominal sum of $140,000.' Germany had obtained the domination in this country through a patent system similar to the chemical patent system and to free the country from that control they were all sold to the Government for what, of course, is an inadequate price if you consider the value to Germany of the control of the wireless news of the world.

"Second, some 5,700 German patents were selected by the Army and Navy as having been taken out by the Germans to control our freedom in waging war. These patents covered gun sights and countless other appliances and devices either used by our army or navy or which might be used in the future. Many of them had been infringed upon by the army and navy in the winning of the war. The Alien Property Custodian turned over to the United States all the German rights and interests as between this Government and German interests to the navy for the nominal sum of $100,000. This transaction will also have to be upset."

Administration's Motives

The President's letter does not specify the purpose to which the patents are to be devoted, assuming, of course, that the proposed proceedings result in forcing the rescission of their sale to the Chemical Foundation. The latter, however, points out that it means the ultimate return to the original German owners since any plan for resale or relicensing by the Government would not be in harmony with our treaty of peace with Germany and Austria.

Charges Met By Counter-Charges

Late Saturday afternoon officials of the Department of Justice voiced a denial of the intimation by Francis P. Garvan that the President's demand for the return of the Chemical Foundation's patents was predicated on information given to the government by lawyers representing the German Cartel. Their conferences in the offices of the Attorney General, it was claimed, were solely in connection with the filing of suits, which had nothing to do with Chemical Foundation matters.

The Government's statement also pointed out that the Department of Justice had decided that the 67 suits instituted by the Chemical Foundation to recover royalties held by the U. S. Treasury might best be handled in the form of one suit in which the government would be the plaintiff instead of the defendant. Another significant statement made by the Department of Justice was that "the return of these patents to the Alien Property Custodian would in no sense benefit their former German owners or interests. The action taken by the Government has been wholly in the interest of the Government itself. The disposition of these patents after their return to the Alien Property Custodian, as well as all alien property held by him must be determined by action of Congress."

Garvan's Refutation

In another long statement issued by the Chemical Foundation, Mr. Garvan replies to the Department of Justice and makes the further charge that its only investigation of the Foundation "was initiated and has been under the direction of Gaston B. Means or Z-13, as he was known during the period when he served Germany under Captain Boy-Ed." He also demanded the "secret" report made to President Harding be made public in order that opportunity might be given to scrutinize the motives behind the government's action.

The refutation of the government's charges are contained in the following paragraphs from Mr. Garvan's statement.

> The naïve explanation of the visits of the representatives of the German Cartel to this country and to the Department of Justice is false. The Germans have had able

lawyers in this country ever since the armistice, and any boy clerk in the office of these attorneys could have attended to the simple filing of these accounting proceedings.

I repeat that the German commission stated that Germany deemed it injudicious for it to attack the title of the Chemical Foundation direct, and that they then urged that these gentlemen in the Attorney General's office persuade the Attorney General and the President to authorize that action and proferred to them all the assistance they could give.

One last falsehood I wish to answer in the anonymous statement issued yesterday. It stated, "It was pointed out that the return of these patents to the Alien Property Custodian would in no sense benefit their former German owners or interests." This statement is also false. No one had ever suggested, so far as I know, that it was the intention of the Government to keep this German property beyond the day when they had satisfied the claims of injured Americans.

The peace treaty with Germany, according to the instructions of the Alien Property Custodian and the Attorney General, ended the Alien Property Custodian's power of sale. They can, therefore, only be held until such time as some arrangement has been made for the securing of American claims, when they must be returned to the German Cartel.

That such action is being contemplated by Congress is evidenced by the fact that Representative Woodruff recently introduced a bill providing for the return to former owners of all German property not exceeding $10,000 in value.

Financial Statement Shows Loss by Foundation

The certified financial statement of the Chemical Foundation submitted in connection with the Shortridge investigation of the dye industry, shows that since its inception in 1919 the Foundation has been operated at a loss of approximately $200,000.

Although the Foundation has received an income of $429,649 it has spent $629,931, of which $264,017 was for "educational literature and pamphlets," $151,268 for office salaries, $84,512 for rent, organization expenses, etc., $43,133 for legal fees in connection with its patents and $26,357 for "general literature and pamphlets."

Over half of the total income, or approximately $245,000, was received from foreign manufacturers importing into the United States products on which the Foundation controlled patents.

It is of interest to know that of the nearly 5,000 patents held by the Chemical Foundation, only 241 have ever paid any royalty. Of these, 31 have paid 67 per cent of the total royalty, 14 have paid 13.8 per cent, 14 have paid 7.2 per cent and 6 have paid 4.2 per cent. In other words, 65 of the 4,802 patents have paid 92.4 per cent of the total income.

Chemical Foundation Activities Cover Wide Range of Utility

In connection with President Harding's demand for the return to the Alien Property Custodian of all patents, trademarks, contracts and other rights by the Chemical Foundation, it is of interest to note the activities in which that organization is engaged.

The primary purpose of the Chemical Foundation is to build up a domestic chemical industry with particular reference to its application to national defense and to the pharmaceutical and medicinal side of the industry. To secure the coal-tar medicinals, it is necessary to have a dye industry, since many medicines could be obtained only at prohibitive expense if they were not developed as byproducts of dye making.

In its efforts to encourage chemical development in the United States, the Chemical Foundation agreed to furnish $25,000 for use this year by the American Chemical Society for the publication of scientific literature. This action was taken when the decrease in receipts of the American Chemical Society made it necessary to reduce the amount of scientific literature it had been publishing.

The Foundation is furnishing $10,000 this year for the National Research Council with which a complete chemical survey has been started. Information is being gathered as to chemical personnel and as to the particular research problems in which the different laboratories are engaging. The survey also includes the compiling of a bibliography of certain chemical subjects and the listing of information with regard to scientific apparatus and chemical supplies.

Another survey being made by the Chemical Foundation has as its objectives the pointing out to individual states the possibilities of developing chemical industries to utilize resources now undeveloped or only partly developed. This survey includes a program for the elimination of waste and the development of chemical byproducts.

Through a co-operative agreement with the Department of Agriculture, the Chemical Foundation is furnishing the necessary funds for work looking to the standardization of biological stains. In encouraging the domestic production of biological dyes, it is felt that an important service is being performed in that the market for these dyes is so limited as to make their commercial production unlikely. Their value to science, however, makes it highly desirable that this country have a source of supply independent of Germany.

With the National Research Council, the Foundation is collecting information as to chemical education. When the survey is complete, it is expected to have in hand full information as to the exact courses of instruction in chemical subjects at all American schools, together with details as to equipment, endowments and the number of students pursuing chemical courses.

The Foundation has an arrangement with the hygienic laboratory of the Public Health Service whereby all salvarsan and other arsenical compounds used for medicinal purposes are tested by the laboratory's chemists before being offered for sale. The Foundation is co-operating with the Fixed Nitrogen Laboratory in research work on the Haber patents, which are among those taken over by the Foundation. The Foundation also has been co-operating with R. C. Tolman, the director of the Fixed Nitrogen Laboratory, in the matter of encouraging Government inventors.

Arrangements recently were completed whereby the Chemical Foundation is to co-operate with the the Bureau of Standards in the setting up of dye standards. The Foundation recently subscribed $1,000 to assist in the preparation of a table of chemical constants, a work being conducted by the National Research Council.

If the Chemical Foundation is allowed to proceed with its program, it is expected to enlarge this type of co-operative work so as to extend help to most of the numerous chemical research laboratories being conducted under government or quasi-government auspices.

Chicago Section, American Ceramic Society, Meets

Spring Meeting in Danville, Ill., Provides Interesting Papers and Inspection Trips

Although rather small in point of attendance, the first meeting of the Chicago section of the American Ceramic Society held outside of Chicago was most successful. About 15 members were present at the dinner at the Plaza Hotel, Danville, Ill., Friday evening, June 23.

Humidity driers were discussed by H. E. Davis of the Northwestern Terra Cotta Co. F. L. Steinhoff, chairman of the section and managing editor of *Brick and Clay Record*, outlined some recent developments in equipment and methods for manufacturing clay products. In an informal talk, E. J. Winkleman, chief engineer of the American Refractories Co., described the Baltimore plant of this company in which certain ideas used in the steel industry have been adapted to the manufacture of magnesite brick. Waste heat boilers utilize heat which is ordinarily lost up the stacks.

In order that the inspection trip through the plants of the Western Brick Co. might be as profitable as possible, Mr. Douthay, general superintendent in charge of production called attention to some of the more important features of the company's operations—stripping by revolving shovel at one plant, the use of hydraulic stripping at another and the mechanical arrangement for pushing cars through the driers.

Norris Blames Muscle Shoals Delay on Fertilizer Trust

Ladd Bill Would Accept Ford Offer—Senator Says It Would Save Farmers $3,000,000 a Year

SENATOR NORRIS, of Nebraska, chairman of the Agricultural Committee of the Senate, who was overridden in his insistence that work in the Muscle Shoals dam should begin July 1, could not resist the temptation on that date to remind the Senate that, as a result of their action, a large number of men who might have been employed, were still without jobs. He addressed his remarks to the people of Alabama, calling attention to the Senate's amendment to the War Department appropriation bill which granted $7,500,000 for the completion of Wilson dam but which included the provision that work should not be started until Oct. 1.

"I hope they will remember," he said, "that those who were giving close attention in the Senate to the Muscle Shoals proposition, and that the Senate, when it passed the appropriation of $7,500,000, would have started that great work to-day, but that because of the great propaganda which influenced the honest and conscientious representatives from the great state of Alabama, and some from the great state of Michigan, where an interested millionaire lives, those men are not working to-day. The Tennessee River is low. The water of the stream is down so that they could do very effective and economical work.

"The effect of the great propaganda that even carried the Senate off its feet was to postpone that great work for a year, and I want the farmers of Alabama, bowed down to the earth with the burdens of the fertilizer trust, to know that through the efforts of their representatives in Congress that great fertilizer trust has been given another year of life to continue to hammer them down to the earth with toil and labor.

Millionaire Senators Helped Delay

"I do not question the motive of any man, either in this body or in the other, because they were carried off their feet, they lost their judgment; but I wish the people of Alabama, the people of Mississippi, the people of Georgia, and of all the South and all the East would look over the roll call when we came to vote on it and see what that roll call means.

I have it in my hand, Mr. President, and while I am not an expert on the financial standing of the various members of this body, as nearly as I am able to determine, I find that the action of the House was confirmed here by a combination of men who were afraid it might be lost if we did not confirm it and by men who did not want anything done, and while it was being done ostensibly from the beginning in the interest of a great millionaire, when it came to the Senate those who were frightened for fear they might lose it were assisted by every millionaire in the Senate, who voted at all, to give this great fertilizer trust another year of life."

In concluding the Senator pointed out the added tax burden imposed on the public by the year's delay in the construction work.

Last Chance for Revised Offers

A final opportunity to offer further modifications to their proposals will be given to all bidders whose offers have been considered by the Senate Agricultural Committee according to Senator Norris' statement after an executive meeting of the committee on Thursday. Letters will be sent to the bidders inviting them to appear at a meeting at his home on July 13.

This course was suggested by several committeemen as a means of finding out whether the bidders have in any way agreed upon modifications.

Ladd Favors Ford Offer

Unconditional acceptance of Henry Ford's offer for the purchase and lease of the Muscle Shoals projects, including the Government's interests in the steam power plants at Gorgas, is provided for in a bill introduced by Senator Ladd of North Dakota. The bill is identical with that introduced in the House by Representative Wright. The bill has the approval of several members of the Senate Agricultural Committee, of which its sponsor is a member.

In introducing the bill Senator Ladd called attention to the expenditures made by American farmers for nitrate importations from Chile and asked if "the farmers should continue to pay more than $3,000,000 annually, when Mr. Ford offers to relieve them of these burdens at Muscle Shoals."

"The average importations of Chilean nitrate for five years, 1911-1915, inclusive," Senator Ladd said, "amounted to 551,714 long tons, with an average value at the Chilean port of $17,511,697, and with an export duty paid to Chile on this tonnage amounting to $6,910,978.92. The cost of ocean freight, insurance, commissions, etc., on this 5-year period of Chilean nitrate importations can be conservatively estimated at $10 a ton, making a total cost at port of approximately $29,939,815.92." Of this tonnage there was consumed as fertilizer by the farmers about 250,000 tons.

"Mr. Ford, in his final offer of May 30, expressly agrees and binds himself throughout the lease period to manufacture nitrogen and other commercial fertilizers, mixed or unmixed, and with or without filler, according to demands, and to produce fixed nitrogen at Muscle Shoals equal to the fixed nitrogen contained in that portion of Chilean nitrate used by the farmers in the 5-year period, 1911-1915."

Marconi Honored by Engineering Societies

Receives John Fritz Medal in Presence of Distinguished Gathering in New York

Senator Guglielmo Marconi received the John Fritz medal on July 6 before a gathering of engineers which filled the auditorium of the Engineering Societies Building in New York. Among the forty distinguished engineers on the platform were Major-General George W. Goethals, Orville Wright, Elihu Thomson and J. Waldo Smith, all of whom have received the same medal.

Senator Marconi received a great ovation as he rose to receive the medal and an even greater acclaim when he concluded his remarks in appreciation of the honor conferred upon him.

"I have long realized that in America, more than anywhere else, the most cordial and generous encouragement is given to an honest endeavor to apply science to useful and practical purposes," said Senator Marconi. "I consider myself fortunate that much of my early work in radio has been carried out in this country, for you realize that wireless communication has become useful, and often necessary, on land and sea, besides tending to increase and simplify the facilities for closer communications between distant people on this earth, thus contributing, I hope, to make good-will take the place of the unrest and mutual suspicion which, unfortunately, seems at present to be a dominating feeling amongst all nations."

Prof. Michael I. Pupin spoke on the progress and prospects for future developments in wireless communication. Prof. C. A. Adams, of Harvard, chairman of the medal committee of the four founder societies, paid a tribute to Marconi's work. James R. Sheffield, for many years Marconi's legal adviser in America, reviewed the life and work of the inventor.

Bureau of Mines Announces Investigation Program

For the fiscal year which began July 1, the Bureau of Mines has at its disposition appropriations totaling $1,580,900. The allotments of that sum for work which includes chemical activities are as follows: Technical work at Pittsburgh experiment station in connection with mine explosions, $53,154; tests of explosives, $50,737; tests of coal mine gases and dusts, $31,655; technical service at Pittsburgh in connection with mineral fuel investigations, $20,210; tests of mineral fuels, $40,890; investigations concerning the preparation and treatment of ores, $32,370; oil shale investigations, $8,920; mining experiments stations, $170,000; study of the chemical technology of oil, $24,040.

Planning for 1923 Meeting of American Chemical Society

Although present interest in American Chemical Society circles centers around the prospects for the September meeting in Pittsburgh it is interesting to note that plans are already forming for the following meeting which will take place in New Haven in April, 1923. The New Haven Section has invited the Connecticut Valley Section to join with them in entertaining the Society.

An executive committee, whose function it is to direct all plans and arrangements, has been chosen by the New Haven Section as follows: Treat B. Johnson, chairman; Blair Saxton, secretary; Arthur J. Hill, C. H. Matthewson, Ralph Langley, J. S. Graveley. Representatives both from outside New Haven in the local section and of the Connecticut Valley Section will be added later.

The meeting of the Society in New Haven will be of special interest, since in connection with this event the new Sterling Chemical Laboratory is to be dedicated by Yale University.

Recent Developments Interest Paper Industry

The Westminster Paper Mill Co., Ltd., has been organized with a capital of $250,000 by Wisconsin capitalists, for the purpose of establishing a mill for the manufacture of tissue paper at New Westminster, B. C. This will be the only paper mill of its kind on the Pacific Coast.

A quantity of pulp wood, about 700,000 ft., is now floating down the Kennebec river for the Pine Tree Pulp Co., a concern established only a few months ago. Ground was broken during the winter for the mill which is located at Gardiner.

The Cushnoe Paper Co. and Kennebec Paper Co., being operated by W. S. Wyman as receiver, are reported as showing a small margin of profit. With a return of normal business conditions, it is expected by Maine paper men that these companies will continue as a factor in Maine's paper production.

There is considerable interest in railroad activities in northeastern Maine. The Great Northern Paper Co. is continuing the building of a logging railroad of standard gauge. Hope is entertained that this eighteen mile road will be completed this season. The Eastern Maine Railroad Co., with charter rights in hand, are considering the question of a railroad from Houlton, in Aroostock County, down the east bank of the Penobscot River to tide water at Bangor where connection will be also made with the Grand Central Railroad. About twenty miles south of Houlton, it is proposed to build a short connecting line to the international boundary near Meductic to connect with the Canadian Pacific Railroad. The proposed road would be about 128 miles in length.

Scientific Photography Now Included in Curriculum

Stockholm University Establishes Complete Laboratory for Technical Photographic Study

Scientific photography is the very latest science added to the subjects studied at the University of Stockholm. Quite recently, Docent Arvid Odencrants, Sweden's leading expert in this line, completed a fully equipped laboratory for scientific photography where the work is now carried on with great intensity and is attracting increasing interest on the part of scientific men and industrial experts in all parts of Sweden.

One of the most important practical aims of the new department is to test and classify the almost innumerable varieties of photographic films, many of them of foreign make, now in the market and to select the best kinds for recommendation to photographers. Films will be graded or classified according to their sensitiveness to light.

The laboratory will also devote itself to the study of photographic apparatus and lighting devices for moving picture purposes. It is closely cooperating with the X-Ray Institute of Stockholm. Important work is also being done in photomicrography, especially in connection with zoology and botany.

Pittsburgh A.C.S. Meeting

Midgley Will Describe Work of General Motors Corporation on Gaseous Detonation

Of outstanding importance in the program of the Pittsburgh meeting of the American Chemical Society will be an address by Thomas Midgley, Jr., of the General Motors Research Corporation on "Chemical Control of Gaseous Detonation with Particular Reference to the Internal Combustion Engine." Mr. Midgley will be assisted by T. A. Boyd. The lecture will include demonstrations of normal combustion and detonation in glass tubes, the suppression of detonation by the addition of certain chemical compounds and demonstrations with an internal combustion engine motor containing quartz windows and apparatus for measuring radiation. The motor will be operated on detonating and non-detonating fuels. Lantern slides will be shown illustrating the periodic variation of anti-knock value among the 16 elements.

"Pittsburgh as a Chemical Manufacturing Center" is the subject of an address to be given by J. H. James, head of the Department of Chemical Engineering, and W. F. Rittman, head of the Department of Commerical Engineering, of Carnegie Institute of Technology. Dr. James will discuss "Pittsburgh's Raw Materials and Markets for Chemical Products." Dr. Rittman will speak on "Pittsburgh's Transportation and Financial Advantages."

By special arrangements, the Committee of the Pittsburgh section of the A.C.S. has obtained dormitory privileges for the councillors at Carnegie Tech. during the Meeting. The Men's Dormitories will be opened to house 350. One of the Women's Dormitories has been offered for the use of the councillor's wives.

Personal

H. B. BRAMLET, First Lieutenant Chemical Warfare Service, was married on June 24 to Miss M. M. DUBOIS. They will be at home after July 15 at Edgewood Arsenal, Md.

C. B. DURGIN has been granted a leave of absence for 6 months from the Bureau of Soils, Washington, to aid in the development work of the Federal Phosphorus Co., Anniston, Ala. Mr. Durgin will be working particularly on the problems of manufacture of high purity phosphoric acid, assisting in the application of the methods for making this material which were developed recently at the Bureau of Soils under the general direction of Dr. W. H. Ross.

WALTER R. HIBBARD has withdrawn from the firm of Burt & Hibbard, Inc., consulting chemists, Bridgeport, Conn., to accept a position in charge of the physical and chemical laboratories of the Winchester Repeating Arms Co., New Haven, Conn.

Prof. H. F. MOORE, of the University of Illinois, addressed the Washington Chapter of the American Society for Steel Treating on June 30, 1922. His topic was "The Fatigue of Metals."

CULLEN W. PARMELEE, professor of ceramic engineering, University of Illinois, has been appointed acting head of the department of ceramic engineering, effective Sept. 1, succeeding E. W. Washburn.

The American Engineering Standards Committee announces the following additions and changes in personnel: F. J. SCHLINK, formerly of the development branch of the engineering department of the Western Electric Co., New York City, has been appointed assistant secretary of the committee. The Electrical Manufacturers Council has appointed A. I. DOREMUS, Crocker-Wheeler Co., New York City, as alternate for A. H. Moore on the main committee of the American Engineering Standards Committee. The Gas Group has appointed W. J. SERRILL, United Gas Improvement Co., Philadelphia, Pa., as alternate for A. H. Hall on the main committee of the A.E.S.C. The U. S. Navy Department has designated Commander HARVEY DELANO, Bureau of Ordnance, Washington, D. C., and Vice-Commander H. F. LEARY to represent the Navy Department on the main committee of the A.E.S.C. The U. S. War Department has appointed Major GLEN F. JENKS, Ordnance Department, U. S. A., Washington, D. C., as alternate to Brigadier General W. S. PIERCE, Ordnance Department, U. S. A., Washington, D. C. on the main committee of the A.E.S.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Coal-Tar Products and Vegetable-Oil Markets During the Second Quarter of 1922

The Trend of Market Developments and Important Price Changes in These Branches of the Chemical Industry

LAST WEEK'S ISSUE contained a review of market conditions for the principal industrial chemicals during the three months ended July 1, 1922. The only significant developments of that period were the general improvements noted in the prices for the more basic commodities and the wide fluctuations in the case of the lesser important and speculative articles. This generalization applies equally well to the coal-tar products market during the second quarter of 1922. Certain of the crudes, such as benzene and phenol showed exceptional strength and favorably affected the market for other crude products. On the other hand, the continued inactivity in the textile centers was reflected by the dormant condition of the intermediate and dye markets. Many of the producers most affected by the slackened demand for staple products have found it profitable to turn their attention to specialties, such as rubber accelerators, photographic chemicals, etc.

Market Developments

Outstanding among the features of this market has been the fact that in the face of unusually large production, benzene prices have been well maintained at comparatively high levels. Most of the producers' business has been in the regular contract requirements of consumers. A few odd lots have appeared in the resale market from time to time and these have brought as high as 40c. per gal. for the 90 per cent test. Quotations were advanced by producers during the interval from 27 to 28c. per gal. for the 90 per cent, and from 29 to 30c. per gal. for the water-white grade.

PRICES OF 35 IMPORTANT COAL-TAR PRODUCTS BY MONTHS, JANUARY-JULY, 1922

Article	Unit	Average Price For Month of— Jan.	Feb.	March	April	May	June	Price on July 1
Benzene, c.p.	Gal.	$0.29	$0.29	$0.29	$0.29	$0.29	$0.30	$0.30
Cresylic acid, 95-97%	Gal.	.60	.45	.45	.48	.48	.50	.51
Dip oil, 25%	Gal.	.31	.27	.24½	.24	.24	.24	.24
Solvent naphtha, water, white	Gal.	.25	.25	.25	.25	.25	.27	.27
Toluene, water white	Gal.	.30	.30	.30	.30	.30	.30	.30
Xylene, pure	Gal.	.40	.40	.40	.40	.40	.40	.40
H acid	Lb.	.97	.90	.85	.85	.85	.85	.85
Phthalic anhydride	Lb.	.37	.37	.35	.36	.35	.35	.35
Salicylic acid, tech.	Lb.	.20	.18	.23	.23½	.25	.25	.25
Alpha naphthylamine	Lb.	.28	.28	.30	.30	.30	.30	.30
Aniline oil	Lb.	.17½	.17	.16½	.16	.15½	.14	.14
Aniline salt	Lb.	.25	.24	.24	.24	.22	.22	.22
Anthracene, 80%	Lb.	.75	.75	.75	.75	.75	.75	.75
Benzaldehyde, U.S.P.	Lb.	1.35	1.30	1.25	1.25	1.25	1.25	1.25
Benzoate of soda, U.S.P.	Lb.	.52	.55	.55	.55	.50	.50	.50
Benzidine, base	Lb.	.85	.85	.85	.85	.85	.85	.85
Benzidine, sulphate	Lb.	.75	.75	.75	.75	.75	.80	.80
Beta naphthol, tech.	Lb.	.31	.29	.28	.27	.25	.23	.23
Dichlorbenzene	Lb.	.06	.06	.06	.06	.06	.06	.06

Phenol is another product to advance under an increasing demand. Material in the hands of dealers early in the year was gradually absorbed and the receipt of orders from foreign sources for large tonnages caused prices to advance from 12¼c. per lb. in April to 15c. for June. Solvent naphtha, cresylic acid, toluene, cresol and salicylic acid have all shown improvement.

A number of declines were noted among the intermediates. Commodities which showed the effect of the unsatisfactory market for dyestuffs include aniline oil and salt, beta naphthol, diethyl aniline and dinitrobenzene.

The Vegetable Oil Market

Practically all of the vegetable oils are in a stronger position than at the beginning of the current year. Part of this has been brought about by the tendency on the part of the industry to discourage hand-to-mouth buying in favor of contracts for deliveries over a period of three to six months.

An important commodity to show the effects of this regular trading was linseed oil. During the early part of 1922 the market was as low as 74c. per gal. Since February, 1922, prices were on a steady advance with the top mark of 90c. per gal. reached during the latter part of May. The summer months have had a tendency to weaken quotations and prices have since receded to 80c. per gal. During the past two weeks the market has shown a marked revival, with recent prices heard around 87c. per gal. for the domestic raw material in carload lots. Cottonseed oil was another item to show a sharp advance since Jan. 1, 1922. The opening quotation was around 7c. per lb. for the crude material, with a steady advance during February and March. Prices have been firmly maintained during the past few months around 9¾@10c. per lb. Corn oil, peanut oil and soya bean oil have also shown considerable activity during the past few months.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	156.67
Last week	157.52
July, 1921	148
July, 1920	274
April, 1918 (high)	286
April, 1921 (low)	140

Six of the twenty-five commodities on which this index is based changed in price during the week. Three—ammonium sulphate, glycerine and linseed oil—were higher, while caustic potash, caustic soda and cottonseed oil contributed to the decline, which amounted to 0.85.

Wages and Hours of Labor in the Petroleum Industry

Some interesting industrial statistics have recently been brought to light in a study made by the U. S. Bureau of Labor Statistics of wages, hours and earnings in the petroleum industry during 1920. Reports were received from the payrolls of plants estimated to represent 25 per cent of the total number of employees engaged in the drilling and operation of oil wells, 50 per cent of all pipe-line employees and 35 per cent of all oil-refinery employees.

The regular working schedule of 74 per cent of all employees at the oil wells was seven days per week, the remaining 26 per cent being six-day workers. On the pipe lines 34 per cent worked 7 days and 66 per cent 6 days. At the refineries, however, but 23 per cent of the employees were 7-day workers and 77 per cent 6-day workers.

The customary hours of work at the wells and on the pipe lines ranged from 8 to 12 per day and at the refineries from 8 to 13. Forty-five per cent of the employees at wells, 43 per cent on pipe lines, and 65 per cent at refineries worked not more than 8 hours per day; 76 per cent at wells, 77 per cent on pipe lines, and 96 per cent at refineries not more than 9 hours; while 85 per cent at wells and 99 per cent on pipe lines, and 99 per cent at refineries worked not more than 10 hours.

It is of interest to note that of 80 refineries located in 15 states and employing 42,537 males and 274 females, women were found in productive work in only 5 establishments, located in 5 states. They were engaged principally in filling and packing bottles, cartons, etc., and only a few were working at common labor.

A summary of the average full-time hours per week and the average earnings per hour are given in the following table. In connection with the wage rates, it should be emphasized that these are the wages in effect in November, 1920, and that in some of the larger establishments substantial reductions have been reported. In most cases reductions meant that a part or the whole of certain war-time bonuses were discontinued.

Occupation	Average Hours Per Week	Average Earnings Per Hour
Wells:		
Drillers	73.6	$1.140
Drillers' helpers and cleanout helpers	59.7	.683
Firemen	57.7	.651
Laborers, roustabouts and connection men	57.7	.589
Pumpers and engineers	62.5	.582
Tool dressers	78.6	.954
Pipe Lines:		
Engineers and pumpers	57.2	.749
Firemen	55.7	.701
Gaugers, deliverymen and oil receivers	58.9	.775
Laborers, roustabouts, etc.	54.7	.528
Line walkers	62.5	.584
Telegraph operators	56 0	.676
Refineries:		
Engineers and chillermen	55.3	.811
Firemen and assistant engineers	53 6	.756
Pumpmen	53.6	.789
Stillmen	54 2	.905
Stillmen's assistants, chargers and leadersup	53 6	.799
Boilermakers	48.1	.991
Boilermakers' helpers	47 6	.741
Laborers	49 7	.575
Machinists	48 5	.905
Pipefitters	49 4	.855
Pipefitters' helpers	48 8	.685

In addition to the statistical sections of the report (Bulletin 297, dated April, 1922) some interesting information is given regarding duties and division of work in the three principal branches of the petroleum industry.

The New York Market

NEW YORK, July 10, 1922.

The chemical market during the past week has shown the effects of the recent holiday period and trading, in general, has been of a desultory character. About 90 per cent of the trade closed from Saturday until Wednesday morning and business was limited to only a few days of full trading. With the exception of a few commodities, there were no features of outstanding interest. Arsenic, tartaric acid, calcium acetate, copper sulphate and ammonium sulphate showed considerable activity, with quotations in some instances fractionally higher. Prussiates, caustic potash, caustic soda and soda ash have revealed no appreciable changes during the interval and quotations were subject to slight shading on firm business.

GENERAL AND SPECIAL CHEMICALS

Arsenic — Domestic producers are quoting higher prices for nearby goods. Importers have also fallen in line with the advancing tendency and only a few odd lots are heard of at 7½c. per lb. The regular range for prime materials is around 7¾@8c. per lb.

Barium Chloride—Leading factors and importers quote spot material at $95@$100 per ton. Goods afloat are held at $92 per ton with shipments at $86.

Bleaching Powder—Prices in general remain unaltered at $1.60 per 100 lb. f.o.b. works for large drums. Imported material is scarce on the spot market and quoted at $1.70 ex store.

Caustic Potash—Imported 88-92 per cent goods have been offered down to $5.50 per 100 lb. for spot delivery. Recent heavy arrivals are responsible for the competition among sellers and lack of interest from consuming quarters. The general range is around 5½@6c. per lb.

Caustic Soda—The export market has shown no activity whatsoever during the past week. Leading producers offer standard brands at $3.70@$3.75 per 100 lb., f.a.s. The movement in domestic circles has been quite satisfactory to dealers and reports show a notable improvement during the month of June. Goods ex-store are held at $3.75 per 100 lbs.

Copper Sulphate—Spot material is practically extinct. The demand is far greater than the available supply and July allotments seem to be well sold up. Quotations range around 6½@6¾c. per lb.

Glycerine—There was a firmer feeling noted in this market due to the lighter offerings from first-hand sources. Chemically pure was a fraction higher at 15c. per lb. Dynamite glycerine was held around 13½c. per lb.

Nitrite of Soda—Trading was along limited lines with imported material quoted around 8¼c. per lb. Domestic producers were holding 9c. per lb. as the regular carlot quotation.

Permanganate of Potash—Imported U. S. P. Crystals were offered at 14½c. per lb. The demand showed little signs of any future activity.

Prussiate of Potash—Prices for yellow material were lower than the last report. Business has not been very encouraging during the interval and sellers offered spot goods at 32c. per lb. The red material still maintains the high figure around 90c. per lb.

Prussiate of Soda—The demand for this material has been rather weak during the past few days and sellers were offering spot goods at 21¼c. per lb. Shipments were quoted at 20c. per lb.

Soda Ash—Prices have shown no appreciable change and prominent dealers were offering carload lots of single bags at $1.75@$1.80 per lb. on spot, with barrels at $1.95@$2 per 100 lb. Contracts remain unchanged.

Sulphate of Ammonia—There has been a pronounced shortage of this material and the market is in a very strong position. Prices for double bags f.a.s have advanced to $3.45@$3.50 per 100 lb.

COAL-TAR PRODUCTS

There have been no signs of any special interest in the crude and intermediate markets during the past week. Large producers of crudes reported a steady call from the various consuming industries with no particular advance or decline along the list. The intermediate market remained in a very dormant state due to the absence of real interest from domestic buyers. Textile mills, it will be recalled, have been operating on an extremely conservative basis of late.

Benzene—Consumers have shown no desire to ease up on the demand for supplies and the producers report an extremely strong market for future business. The pure material is quoted at 30@35c. per gal. with 90 per cent at 28@31c. per gal. Spot lots are held by second hands at 40c. and higher for the 90 per cent grade.

Beta Naphthol—Sales of technical material were recorded at 23c. per lb. Producers are somewhat higher and quote the market at 24c. Competition remains keen for any passing business with prices subject to shading.

Cresylic Acid—A continued active inquiry has kept the market in a very firm position. Supplies of domestic and foreign goods are rather light on spot, with the 97-99 per cent domestic held at 56@58c. per gal. and 95-97 per cent at 51@53c. Imported high test goods sold up to 65c. per gal.

Paranitraniline — Inquiries have recently been received in satisfactory volume and sales are reported at 75c. per lb. The general range is from 75@80c. per lb.

The St. Louis Market

ST. LOUIS, July 6, 1922.

During the past two weeks activities in the industrial chemical market have been somewhat quiet, but this is only to be expected at this time of the year. We do not believe, however, that this lull will prevail for as long a period as in previous years, as stocks on many items are still being carried on a minimum basis and replacements must be made more frequently. The tone of the market remains quite steady, with a few advances since our last report. Imported chemicals are inactive.

ALKALIS

The *caustic soda* market has been rather quiet since our last report. Small quantity purchases are about nominal with nothing of a carload nature to report. Prices have not fluctuated, flake caustic in single drum lots holding around $4.50 per 100 lb., while solid can be bought at $4. *Soda ash* has done nothing unusual for some time. There has been no tendency toward price fluctuation or an increased or decreased demand. *Bicarbonate of soda* is at present the wild member of the alkali group in so far as it is impossible to say at any time at what price it can or cannot be bought. Replacement goods, however, are somewhat stronger and should have a tendency to stabilize the market. *Sal soda* has recently stiffened a bit and no price cutting has been felt recently. A good volume of business is being done in this item. Prices for barrels are $1.75 per 100 lb., while package goods sell at $2.15 per case.

GENERAL AND SPECIAL CHEMICALS

Producers of heavy mineral acids report a continued improvement in this line, with prices much stronger. *Carbolic acid*, medicinal grade, is moving very well and prices are firm. *Citric acid* manages to keep pace with last year, with spot stocks of domestic material still very scarce. Further advances have been made in *oxalic acid* due to the increased cost of basic material. Last week prices ranged from 14½@16c., the demand being very good with a fairly large expansion over a month ago. *Tartaric acid* is coming to life and some very substantial orders have been placed during the past two weeks, prices remaining at the former levels. *White arsenic, powdered*, is very strong and is now being quoted at 7¾c. f.o.b. New York with a short supply and large demand. *Carbon disulphide*, being a seasonable article, is showing up very well and in all probability will continue to do so, as we are now arriving at a season when it will be used quite extensively in the agricultural districts of the country in destroying boll weevil and other insects infesting crops. *Carbon tetrachloride, technical*, is moving in a routine way. Some time ago the demand for *coppéras* was far in excess of supplies; however, today supplies have been increased and spot stocks are available at $18@$20 per ton in carload lots f.o.b. producers' works. There has been considerable action in the *glycerine* market since our last report. This being a time of contract making, some changes are naturally expected. One producer was offering contracts for six months, with protection against decline, at 14c., basis drums, others as low as 14⅜c. on contracts for a few days only—spot goods at 14½c.—and then suddenly back to 15c. for both contract and spot. At present the price of 15c. seems firm and will undoubtedly be rock bottom for six months to come. There has been no change in the *potash cyanide* situation, stocks still being limited and the demand routine. *Zinc sulphate, technical*, is in very good demand and there are persistent rumors of an advance.

VEGETABLE OILS AND NAVAL STORES

Turpentine has covered a large range of prices recently, the peak being $1.54 per gal. in single barrels, but it has gone downward again and can now be had at $1.30. *Linseed oil* is moving in good volume now, owing to increased activity in the paint industry. Prices have not changed noticeably. *Castor oil* is still being held at 12¾c., with a normal volume of business being transacted.

The Iron and Steel Market

PITTSBURGH, July 7, 1922.

While the actual tonnage of output of pig iron and steel may not be increasing at the moment, on account of weather conditions usual in July and August, the capacity of production units in operation still tends to increase. The number of furnaces in blast increases from week to week. For instance, last week the Republic Iron & Steel Co. blew in a third stack at Youngstown while on July 5 it put in operation its bessemer department, idle since last September.

STEEL INGOT PRODUCTION

Production of steel ingots averaged in May a rate of about 38,250,000 gross tons per annum, and the rate in the past fortnight, counting out time lost by the holiday, which was observed at most plants Monday as well as Tuesday, was probably about 40,000,000 tons, which compares with a rate of about 35,000,000 tons on April 1, when the coal strike started, and a rate of about 20,000,000 tons last December.

Inasmuch as it is unprofitable to blow in a blast furnace for a short period, the continued addition of stacks to the active list is proof that the iron and steel trade feels confidence as to the future not only of its coke supplies but also of its fuel supplies, as it is useless to make pig iron unless there is fuel for power and heating steel. If an actual shortage of coal is looked for, therefore, it appears that it should be sought elsewhere than in the iron and steel industry. There is no circumstantial evidence, furthermore, that any shortage has developed among consumers of steel, as buyers are still pressing steel mills for deliveries.

As to tonnage turnover, the finished steel market is now decidedly quiet, as it almost invariably is in July and August. The dullness gradually stole over the market during June. The steel industry, as to production and consumption, is wound up to run well for the next 2 or 3 months on the basis of engagements already made, and does not require that there be market activity at the present time. The question is solely as to the more distant future. To date there has been no menacing accumulation of steel in the hands of buyers. Production of steel ingots in 1921 was about 19,000,000 tons, while the drastic liquidation of stocks of steel in buyers' hands and of manufactured wares probably represented all of 3,000,000 tons, making 22,000,000 tons a fair guess as the representation of consumption. An increase of only 25 per cent in consumption in the past 6 months over the average of 1921 would require almost 14,000,000 tons of ingots, while production in the 6 months has been 16,000,000 tons. The difference of 2,000,000 tons might represent replenishment of badly depleted stocks and provision of stocks for the filling of actual orders at manufacturing plants consuming steel. The accumulation may be even less than here suggested.

IRON AND STEEL PRICES

The market stands substantially as follows: Bars, shapes and plates, 1.60@1.70c.; hoops and bands, 2.40@2.50c.; standard steel pipe, 71 per cent basing discount; nails, $2.40@$2.50; blue annealed sheets, 2.40@2.50c.; black sheets, 3.15@3.30c.; galvanized sheets, 4.15@4.30c.; automobile sheets, 4.50@4.85c.; tin plate, $4.75. Fabricated wire fence has been reduced about $4 a net ton, the discount on jobbers' carloads being increased from 71½ per cent to 73 per cent. Demand has been relatively light for a long time.

While a few sales of sheet bars were reported recently at $37.50@$38, the common settling price now is $35. The Carnegie adjustment price for third quarter, on regular contracts, is understood to be $33, against $31 for second quarter and $30 for first quarter. Billets and slabs are quotable at $35, by inference from sheet bars, there being no open market transactions of note.

Wire rods, which had been at the practically nominal price of $38, have been advanced to $40, and even at this price producers are indisposed to sell except to regular customers.

Pig iron continues quiet as to actual turnover. In several districts asking prices have advanced slightly in the past week or two. The valley market is unchanged, with prices practically nominal at $25 for bessemer and basic and $24 for foundry, f. o. b. valley furnaces. On the whole the valley market does not seem to be as firm as 30 days ago. Freight from valleys to Pittsburgh came down July 1 from $1.96 to $1.76.

Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.14 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1 00
Benzaldehyde U.S.P.	lb.	1.25 — 1 30
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.50 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.23 — .25
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99% straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.20 — 22
Dinitroclorbenzene	lb.	.22 — 24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — .95
Meta-phenylenediamine	lb.	.95 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.00 — 1.20
Naphthalene crushed, in bbls.	lb.	.06 — 06¼
Naphthalene, flake	lb.	.06 — 07
Naphthalene, balls	lb.	.07¼ — 08
Naphthionate of soda	lb.	.58 — 65
Naphthionic acid, crude	lb.	.65 — 70
Nitrobenzene	lb.	.10 — 12
Nitro-naphthalene	lb.	.30 — 35

Nitro-toluene	lb.	.15 —	.17
N-W acid	lb.	1.15 —	1.30
Ortho-amidophenol	lb.	2.40 —	2.50
Ortho-dichlor-benzene	lb.	2.15 —	.20
Ortho-nitro-phenol	lb.	.70 —	.75
Ortho-nitro-toluene	lb.	$0.10 —	$0.13
Ortho-toluidine	lb.	.14 —	.18
Para-amidophenol, base	lb.	1.25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.75 —	.80
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	.90 —	1.00
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.14 —	.15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.75 —	1.80
R-salt	lb.	.60 —	.70
Salicylic acid, tech., in bbls	lb.	.25 —	.25½
Salicylic acid, U. S. P	lb.	.26 —	.26½
Solvent naphtha, water-white, in drums, 100 gal	gal.	.27 —	.32
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 —	.18
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Beeswax, pure white	lb.	.38 —	.40
Japan	lb.	.17 —	.17½

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

FORT PAYNE—The Clay Products & Mining Corp., 150 East State St., Trenton, N. J., recently organized with a capital of $1,500,000, is arranging for the immediate development of over 150 acres of clay and kaolin properties, lately acquired in this district, and will install a complete operating and producing plant. R. M. J. Smith is president; and Alfred L. Eccles, secretary.

California

IRVINGTON—The Panama Soap Co. has concluded negotiations with the local Chamber of Commerce for the acquisition of a factory site, and will soon prepare plans for the erection of a new plant, estimated to cost about $60,000, including equipment. The Chamber of Commerce is interested in the project.

OWENSMOUTH—The Standard Oil Co. of California, 200 Bush St., San Francisco, has plans under way for the construction of a local distributing plant, to include a number of 1-story buildings, to cover more than one acre of ground. Work will be commenced at an early date.

SELMA—The Fresno Tire & Rubber Co., Mattei Bldg., Fresno, has awarded a contract to W. L. Miller, Los Angeles, for the erection of its proposed new plant at Selma, to be 3-story, 60x250 ft., and estimated to cost about $125,000, including machinery. It will be equipped for the manufacture of tires and other rubber products. John S. Bates, Rowell Bldg., Fresno, is engineer.

SANTA BARBARA — Considerable special machinery will be installed in the new addition to be erected at the flour milling plant of the Santa Barbara Milling Co., to be 23x90 ft. A. J. Wehrle is general manager.

BAKERSFIELD—The Associated Oil Co. and the Associated Supply Co., affiliated organizations, have plans nearing completion for the erection of a new oil distributing plant at 32nd and Chester Sts., a site recently acquired. It will include oil tanks, storage and pumping facilities, etc., and is estimated to cost about $60,000. Headquarters of the first noted company are in the Sharon Bldg., San Francisco.

Illinois

NORTH CHICAGO—The Chicago Hardware Co. is taking bids on a general contract for the erection of a 1-story addition, 70x100 ft., to be equipped as an enameling plant. It is estimated to cost about $40,000. Shankland & Pingrey, 209 South La Salle St., Chicago, are engineers.

Indiana

HAMMOND—A 1-story foundry, 60x130 ft., will be erected by the Calumet Tank & Mfg. Co., on Industrial Road, estimated to cost about $75,000, including equipment. E. R. Kyler is president and treasurer.

INDIANAPOLIS—The Chapman Price Steel Co., Shelby St., has preliminary plans in progress for the erection of a large addition to its plant, comprising a number of buildings, estimated to cost about $500,000, including equipment. Niles Chapman is president.

GARY — The National Tube Co., Frick Bldg., has completed plans for the erection of the initial units of its proposed new steel mill here, estimated to cost in excess of $1,000,000. R. C. Patterson is company engineer; W. E. Schiller is president.

Kentucky

LOUISVILLE—The Producers Wood Preserving Co., an interest of the Ayer & Lord Tie Co., 39 East Jackson St., Chicago, Ill., has broken ground for the erection of a new creosoting plant, estimated to cost about $200,000, including equipment. The Leonard Construction Co., 37 South Wabash Ave., Chicago, has the general contract. Oscar S. Bond, Marion E. Taylor Bldg., Louisville, is in charge.

Louisiana

HOUMA—The Industrial Committee of the Houma-Terrebonne Association of Commerce, J. H. Thatcher, chairman, is developing plans for the location of an industry at Houma to manufacture synthetic marble from crushed oyster shells. A site for the proposed plant is being selected.

MONROE—The Ouachita Natural Gas & Oil Co., P. O. Box 1199, has preliminary plans in progress for the construction of a new pipe line, with auxiliary equipment, from Swartz to Sterlington, La., for use in connection with its gasoline absorption plant and carbon works, about 9½ miles long, estimated to cost about $60,000.

Maryland

EASTON — The New Brick & Tile Co., Moreland Bldg., will break ground at once for the erection of its proposed new plant on local site for the manufacture of brick and tile products. It will consist of a main 1-story building, and is estimated to cost about $45,000. The company was organized recently under state laws, with a capital of $50,000. O. Fletcher Clark is secretary and treasurer, and Frank Ross, superintendent.

Massachusetts

MALDEN — Wadsworth, Howland & Co., Inc., 139 Federal St., Boston, manufacturer of paints, varnishes, etc., has acquired property adjoining its Malden works on Green St., totaling about 28,600 ft., and another site in the vicinity, aggregating 200,000 ft., and will use the land for expansion. The proposed new buildings are expected to cost in excess of $500,000. The last noted property will be used for the erection of a power plant.

AMHERST—Bids on a general contract have been taken for the erection of a new 3-story and basement chemistry and physics building at the Amherst Agricultural College, to be 94x195 ft. Ritchie, Parson & Taylor, Boston, are architects.

Michigan

MUSKEGON—The Central Paper Co. has tentative plans under consideration for the erection of a 3-story addition to its mill on Richard St., estimated to cost about $200,000, including machinery. E. J. Geddes is secretary.

LANSING—The Capital Glass Co. has completed the erection of a new local plant and will commence operations at once for the manufacture of mirrors and other glass products, primarily for automobile service.

KALAMAZOO—The Kalamazoo Vegetable Parchment Co., manufacturer of parchment papers, has awarded a contract to H. L. Vanderhorst, Grand Rapids National Bank Bldg., Grand Rapids, for the erection of the proposed new addition to its mill, to be 2-story, 2-machine capacity, estimated to cost about $400,000, including machinery. Billingham & Cobb, Press Bldg., Kalamazoo, are architects; J. Kindleberger is president and manager.

Missouri

KANSAS CITY—The Central Paper Box Co., 2935 Belleview Ave., has completed plans and will soon break ground for the erection of a new 2-story and basement plant, 125x150 ft., on Belleview Ave., near 29th St. Hans Von Unwerth, 500 Reliance Bldg., Kansas City, is architect.

New Jersey

TRENTON—The Resolute Pottery Co., 3rd St., manufacturer of sanitary earthenware, has filed plans for the erection of a 1-story plant addition to cost about $10,000.

NEWARK—The Premier Rubber Co., recently organized with a capital of 50,000 shares of stock, no par value, to manufacture a general line of rubber specialties, has acquired the factory at 218-24 New St., at Hoyt St., under a 5-year lease. Possession will be taken at once and equipment installed. It is proposed to have the plant ready for service early in August. The company is headed by John W. Stoddard and W. Howard Demarest, 790 Broad St., Newark.

NEWARK—Fire, June 26, damaged a portion of the plant of L. Mundet & Co., Long Ave., Hillside section, manufacturers of cork products. An official estimate of the loss has not been announced.

New York

NEW YORK—The American Smelting & Refining Co., 120 Broadway, has preliminary plans under way for the erection of a new byproducts coke plant on site selected in the Coahuila district, Mexico, estimated to cost in excess of $5,000,000, including machinery. The proposed plant will consist of a series of buildings, to be equipped for different features of production. William Loeb, Jr., is vice-president in charge.

NEW YORK — The International Carbon Corp., operated under the direction of the Atlas Powder Co., 200 Fifth Ave., and the Columbian Carbon Co., is considering plans for the establishment of a foreign branch plant on site to be selected in France. The company specializes in the production of a decolorizing carbon, known as "Darco," and has succeeded to the business of the Darco Corp., with plant at Marshall, Tex., recently placed in operation. A common stock issue of $1,210,000 is being sold, the proceeds to be used, in part, for the proposed expansion.

New Mexico

RATION—The Ideal Mining & Milling Co. has tentative plans under consideration for the erection of a new flotation plant at its local properties, to have an initial output of about 50 tons a day. A number of improvements are now being made at the works, including the installation of new machinery.

SILVER CITY—The Tonopah-Belmont Co., Tonapah, Nev., has acquired the properties of the Wyman Silver Mining Co., near Silver City, and plans for extensive development and production. Equipment for this purpose will be installed at an early date.

North Carolina

WINSTON-SALEM—The Engineering Division, Department of Public Works, has plans under way for the installation of new filtration equipment at the municipal waterworks. A coagulating basin, six filters, ariator, washing tower, and other equipment will be installed. Bids are expected to be asked early in August.

BALDWIN—The National Soapstone Co., First National Bank Bldg., Roanoke, Va., has awarded a general contract to the Virginia Bridge & Iron Co., Roanoke, for the erection of a new plant at Baldwin, consisting of three buildings, 60x115 ft., 30x45 ft., and 30x45 ft., respectively. A list of equipment for installation has been arranged, and this feature of the work will be arranged at an early date. C. R. Williams is general manager.

Ohio

OAK HARBOR—The Liberty Cut Glass Co. is arranging for extensions in its plant to double, approximately, the present output. Considerable new equipment will be installed. J. H. Fisher is general manager.

WARREN — The Youngstown Steel Co., Realty Trust Bldg., Youngstown, O., has awarded a contract for the clearing of the site at Warren, for the construction of its proposed new steel mill, estimated to cost in excess of $2,500,000. Plans for the plant are in course of preparation. H. Z. Bixler is company engineer in charge.

Oklahoma

ADA—The Oklahoma Portland Cement Co. is making a number of improvements and extensions in its local mills, and is completing the installation of a second kiln in its recently constructed "wet process" plant. The other mill, or "dry process" plant, will be overhauled at once. Work is under way on a new power plant.

MUSKOGEE—The Oklahoma Producing & Refining Co., a subsidiary of the Pure Oil Co., is considering tentative plans for extensions in its local oil refinery. The expansion will be designed to handle the output of the Oklahoma Central Oil Co., recently acquired for a consideration said to be close to $5,000,000, and with production approximating 5,400 bbl. daily.

Pennsylvania

NEW CASTLE—The Elliott-Blair Steel Co. is planning for the erection of an addition to its plant, consisting of a number of buildings, estimated to cost in excess of $200,000, including equipment.

PHILADELPHIA—H. Swoboda & Son, Inc., 1027 North Bodine St., manufacturer of leather products, has foundation work under way for the erection of a 1-story

addition to its plant to cost about $50,000. G. Swoboda is president.

PHILADELPHIA—Fire, June 25, destroyed a portion of the storage and distributing plant of the Pennsylvania Synthetic Gas & Chemical Co., 63rd St., near Chester Ave., with loss approximating about $15,000.

Tennessee

CRAB ORCHARD — The Southern States Lime Corp. is said to be planning for the erection of a new hydration plant to cost about $20,000. N. D. Walker is general manager.

HARRIMAN—The City Council is considering the installation of a new filtration plant at the municipal waterworks. J. C. Laird is city engineer.

Texas

REFUGIO—The Refugio Glass Works, Inc., National Bank of Commerce Bldg., San Antonio, Tex., recently organized with a capital of $75,000, has selected a site at Refugio, near San Antonio, for the erection of a new plant for the manufacture of high pressure glass bottles, glass panels and kindred specialties. Work will be commenced at once, and it is proposed to have the plant ready for operation early in the fall. W. L. Napier is manager.

DALLAS—The Texas Chinaware & Novelty Pottery Co., recently organized with a capital of $50,000, will soon commence the erection of a new plant at Betterson Circle, Oak Cliff district, for the manufacture of whiteware, china tops and other pottery products. The initial works will consist of 3 pottery kilns and 3 kilns for bisque ware. The new company is headed by H. G. Stern, J. D. Robinson and P. A. Angelsburg.

STAMFORD—The Stamford Cotton Oil Co. is reported to be planning for the rebuilding of its local plant, partially destroyed by fire, June 23, with loss estimated at about $40,000, including equipment. J. L. Jones is president, and W. A. Ernest, general manager.

WEST DALLAS—The Clayton Refining Co. has remodeling work under way on the local oil refinery, formerly operated by the Hercules Refining Co. The plant will be increased to develop a daily capacity of about 5,000 bbl. The work is estimated to cost about $45,000.

ELECTRA—D. E. DeCourse, Devol, Okla., and associates, have acquired the local oil refinery of the Beaver Electra Refining Co., for a consideration stated at $95,000. The new owners will organize a company and operate the plant. It is proposed to make a number of improvements and extensions.

West Virginia

BELLE—The Belle Alkali Co. will soon commence the erection by day labor of its proposed 2-story plant addition, 50x100 ft., to be equipped for the manufacture of caustic soda, chlorine, etc., estimated to cost close to $100,000. D. W. Stubblefield is general manager.

Industrial Developments

GLASS—The United States Window Glass Co., Jewella, near Shreveport, La., has placed its new local plant in operation, and will give employment to a working force of about 750 men. The factory was completed recently at a cost of close to $3,000,000.

The Interstate Window Glass Co. has resumed partial operations at its Plant No. 3, following a suspension for more than a year past. Tank fires have been started and it is expected to place the entire plant in full operation by August 1, giving employment to about 200 men. It is said that orders on hand insure continuous production for a considerable period. The company is also arranging for the early resumption of manufacture at its plant at Okmulgee, Okla., and it is expected to through this entire plant in service during July. Tank fires have been lighted.

Manufacturers of glass bottles and containers in the vicinity of Vineland, N. J., report an improved demand for production, and surplus stocks are being depleted rapidly. Opal ware and kindred material containers are in demand considerably in excess of normal.

CERAMIC—The John S. E. Pardee Co., Maple Shade, N. J., manufactuer of brick, is operating under maximum production, with a full working force. The company has just completed the installation of a new brick-making machine to provide an additional output of about 40,000 bricks per hour.

J. E. Thompson, recently appointed receiver for the Guernseyware Co., Cambridge, O., manufacturer of vitrified chinaware products, will continue the plant in operation.

OIL—Gosden & Co., Bigheart and Tulsa, Okla., has advanced production at its refineries from 35,000 to 40,000 bbl. per day.

Following refinancing the Constantine Refining Co., Tulsa, Okla., is planning for the resumption of operations at its plant at Devol, and in the district west of Tulsa. It is expected to develop full capacity at an early date.

IRON AND STEEL—The Reading Iron Co., Reading, Pa., has increased production to the highest point within the past 24 months. All plants at Pottstown, Columbia, Danville and Birdsboro, are now in service, giving employment to a working force about 75 per cent of normal. Operations were recently resumed at the eight furnaces at the Glasgow puddle mill of the company, following a shut down for more than a year past.

The Carnegie Steel Co., Pittsburgh, Pa., is now operating 38 blast furnaces, against a total of 35 on May 5, and 34 early in April, at the commencement of the coal strike. It is planned to add to the list of active stacks at an early date. At its Union mills, the company has increased the operating schedule to 90 per cent of normal, while the Ohio works have 14 open-hearth furnaces in service, with a production basis of 93 per cent of normal.

The Gulf States Steel Co., Gadsden, Ala., is maintaining production at close to normal at its local mills. The wages of mill men have been advanced 10 per cent, effective July 1.

Blast furnace operations in the Mahoning and Shenango Valley districts of Ohio are now at the highest point of any time within the last 18 months. In the first noted section, 18 out of 27 stacks are in service, bringing production to a point of 80 per cent of normal; in the Shenango Valley, 8 out of 20 stacks are on the producing list.

Following a shut down for close to two years past, the Bon Air Coal & Iron Corp., Nashville, Tenn., is arranging to blow in its blast furnace at Allen's Creek around the middle of July. The wood distillation plant of the company at Lyles will be placed in service at the same time, after a similar idle period.

The Wheeling Steel & Iron Co. has advanced production from 45 to 75 per cent of normal at its Benwood, W. Va., plants, adding about 400 men to the working force. The company has placed an additional sheet metal in service at the plant of its Whitaker-Glessner division, Martin's Ferry, O., bringing manufacture up to about 66 per cent of normal.

COKE — The Woodward Iron Co., Birmingham, Ala., is arranging for the operation of 30 more byproduct coke ovens at its plant, bringing the active list up to 200 ovens. The company is operating 4 blast furnaces.

Coke production in the Connellsville, Pa., district is being increased. During the last week in June, 3 plants resumed operations, bringing the number of active plants up to 39. Production in this section has been advanced from 58,663 to 66,850 tons per week.

Arrangements are being made for the early resumption of operations at the coke ovens in the vicinity of Dawson, N. M., which have been closed down for about 2 years past. About 200 ovens are available for immediate lighting.

The H. C. Frick Coke Co., Connellsville, Pa., is increasing operations at its different plants. A total of 50 ovens have been lighted at the Leisenring No. 1 Plant; 40 ovens have been started at the Lomond No. 2 Plant; and 50 ovens have been placed in blast at the Oliphant works.

MISCELLANEOUS — The Lehigh Portland Cement Co., New Castle, Pa., has advanced production to a full capacity basis, with full working force, at its 3 local mills.

The Barrett Co., Philadelphia, Pa., manufacturer of prepared roofing, paper products, etc., has increased the wages of employees at its Elizabeth, N. J., works 10 per cent. About 200 operatives are affected.

The Chino Copper Co., Silver City, N. M., is increasing operations at its properties, and is now giving employment to about 700 men.

The Vanadium Corp., Pittsburgh, Pa., manufacturer of ferro-vanadium, etc., has recently resumed operations at its plant at Bridgeville, Pa.

The Mathieson Alkali Works, Providence, R. I., is running at about 80 per cent of capacity at its plants. Following the recent acquisition of the Commonwealth Co., plans for extensive production are being developed in the line of general chemicals, supplementing the current manufacture of caustic soda, chlorine and bleaching powder.

Capital Increases, Etc.

THE W. H. LOOMIS TALC CORP., Gouverneur, N. Y., has filed notice of increase in capital from $148,000 to $173,000.

THE MORGAN CHEMICAL CORP., Ogdensburg, N. Y., has filed notice of dissolution.

THE ATLANTIC REFINING Co., 3144 Passyunk, Philadelphia, Pa., operating a local oil refinery, with similar plants at Franklin and Pittsburgh, Pa.; and Brunswick, Ga., is disposing of a bond issue of $15,000,000, a portion of the proceeds to be used for general expansion and operation.

THE BRIDGEPORT BRASS FOUNDRY, INC., Bridgeport, Conn., has filed final notice of company dissolution.

The plant and property of the CENTURY-PLAINFIELD TIRE Co., Plainfield, N. J., manufacturer of tires and other rubber products, will be sold by the receiver, Charles R. McNair, 147 Ellison St., Paterson, N. J.

THE TEXIGAN OIL PRODUCTS Co., Saginaw, Mich., has filed notice of increase in capital from $100,000 to 150,000.

THE MINER-EDGAR Co., Blanchard St., Newark, N. J., manufacturer of chemicals and producer of paper clays, has arranged for a bond issue of $1,500,000, a portion of the proceeds to be used for expansion and additions to working capital. Henry M. Miner is president.

HOLTON & Co., Detroit, Mich., a Delaware corporation, have filed notice of change of name to the Century Oil Co., at the same time increasing their capital from $100,000 to $250,000.

THE MUTUAL SERVICE OIL Co., Cleveland, Ohio, has filed notice of increase in capital from $100,000 to $250,000, for proposed expansion.

THE WARREN FOUNDRY & MACHINE Co., Phillipsburg, N. J., has filed notice of change of name to the Warren Foundry & Pipe Co., to devote operations to the manufacture of cast iron pipe, and other foundry products.

THE SAGUENAY PULP & POWER Co., Montreal, Que., is arranging for a bond issue of $6,400,000, a portion of the proceeds to be used for general expansion.

THE PUBLIC SERVICE GAS Co., Newark, N. J., operating artificial gas plants, has been granted permission by the Public Service Commission to issue additional capital stock in an amount of $2,500,000, a portion of the proceeds to be used for extensions and betterments.

William C. Matlack has been appointed temporary receiver for the RARITAN ANILINE WORKS, Raritan, N. J., manufacturer of aniline oils and kindred specialties.

THE AMERICAN LIME & STONE Co., Bellefonte, Pa., operating a local lime manufacturing plant, is disposing of a bond issue of $1,100,000, a portion of the proceeds to be used for plant extensions and betterments. Work is under way on one of the largest single lime-burning plants in this country at Bellefonte. The company is operated by the Charles Warner Co., Wilmington, Del. Charles Warner is president of both organizations.

Charles N. Codding, Elizabeth, N. J., and William H. Dieker, Jersey City, N. J., have been appointed receivers for BYRON HEFFERMAN & Co., manufacturers of camphor substitutes, with plant in the first noted city.

THE AVRI DRUG & CHEMICAL Co., 421 Johnston Ave., Jersey City, N. J., has filed an involuntary petition in bankruptcy.

New Companies

THE BLUE & WHITE SOAP Co., Boston, Mass., has been incorporated with a capital of $50,000, to manufacture soaps. David Harvey is president, and Abraham Superior, 89 Humboldt Ave., Boston, treasurer.

WILLIAM G. MULLER, INC., New York, N. Y., has been incorporated with a capital of $200,000, to manufacture chinaware products. The incorporators are William G. Muller, F. Heinrich and W. G. Bushell, 67 Wall St., New York. The last noted represents the company.

THE OIL PRODUCTS Co. OF BALTIMORE, INC., 302-4 North Holliday St., Baltimore, Md., has been incorporated with a capital of $35,000, to manufacture oils, paints, etc. The incorporators are John G. Platt, Alton L. Kibler and James B. Thompson.

THE KENTUCKY CARBON & CHEMICAL Co., Louisville, Ky., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are Harry Reid, Indianapolis, Ind., Robert G. Gordon and Owsley Brown, Louisville.

THE ASBESTOS FIBRE Co., New York, care of S. V. Elting, 46 Cedar St., represent-

ative, has been incorporated with a capital of $275,000, to manufacture asbestos products. The incorporators are A. Harnick, L. A. Fleischer and G. Levy.

THE ATLANTIC GLASS MFG. CO., care of the Corporation Trust Co. of Delaware, Wilmington, Del., representative, has been incorporated with a capital of $500,000, under state laws, to manufacture glass products.

THE CEROX MINERAL PAINT CO., 2528 West 48th St., Chicago, Ill., has been incorporated with a capital of $75,000, to manufacture paints and kindred products. The incorporators are Louis G. Hughes, J. B. Harris and John R. Nelson.

THE LIGHTNING PRODUCTS CO., 79 Williams St., Orange, N. J., has been incorporated with a capital of $125,000, to manufacture polishes and kindred products. The incorporators are Albert Kellerman, Louis I. and Bernhard Shapiro.

THE DEERFIELD VALLEY PAPER CO., Portland, Me., has been incorporated with a capital of $650,000, to manufacture paper products. E. U. Mann is president; M. D. Mills, treasurer; and Charles D. Booth, Portland, representative.

THE THOMAS OIL CORP., Houston, Tex., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under state laws, with a capital of $100,000, to manufacture petroleum products. The incorporators are S. M. Griffin, O. S. Thomas and B. A. Perryman, all of Houston.

THE NORTH RIVER CHEMICAL CO., New York, N. Y., care of A. J. Levine, 299 Broadway, representative, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are G. W. Frederick, E. Moser and S. A. Junghans.

THE OWENSBORO WALL PLASTER CO., Owensboro, Ky., has been incorporated with a capital of $5,000, to manufacture plaster and kindred products. The incorporators are J. T. Harrison and P. A. Yager, both of Owensboro; W. L. and E. H. Delker, both of Henderson, Ky.

THE EATON, CRANE & PIKE CO., Pittsfield, Mass., operating a local mill for the manufacture of paper products, has filed articles of incorporation under state laws, with capital of $3,500,000, to provide for proposed expansion. Arthur W. Eaton is president; and William H. Eaton, treasurer, both of Pittsfield.

THE EDWARD NEWBY OIL CO., Houston, Tex., care of H. G. Eastburn, Ford Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws, with capital of $1,000,000, to manufacture petroleum products. The incorporators are E. E. Newby, Houston; J. C. Hought and I. H. Schwartz, both of Indianapolis, Ind.

THE SOUTHERN FERTILIZER WORKS, Orlando, Fla., has been incorporated with a capital of $100,000, to manufacture commercial fertilizer products. T. L. Payne is president; J. P. Williams, vice-president; and R. H. F. Dade, secretary, all of Orlando.

THE PENDLETON OIL MILL, INC., Pendleton, S. C., has been incorporated with a capital of $50,000, to manufacture oil products. E. N. Sitton is president; Cema Chreitzberg, vice-president; and B. M. Aull, secretary, all of Pendleton.

THE CHASY LIMESTONE CORP., New York, N. Y., has been incorporated with a capital of $300,000, to manufacture lime and operate limestone properties. The incorporators are H. C. Jeffries, W. H. Higginbotham and W. H. Williams, 32 Nassau St., New York, the last noted represents the company.

THE WOOD COUNTY COTTON OIL CO., Mineola, Tex., has been incorporated with a capital of $56,000, to manufacture cotton oil products. The incorporators are W. W. Perry, R. Bergfield and H. W. Meredith, all of Mineola.

THE COMMERCIAL WALL PAPER MILL, INC., 1416 South Talman Ave., Chicago, Ill., has been incorporated with a capital of $250,000, to manufacture wall papers and other paper products. The incorporators are James E. Hauronic, R. S. Tuthill and Frank P. Page.

THE INTERNATIONAL SUGAR CO., Washington, D. C., care of the Delaware Registration Trust Co., 900 Market St., Wilmington, Del., has been incorporated under Delaware laws, with a capital of $21,000,000, to operate sugar refineries. The incorporators are Howard Allen, Charles E. Wynne and Frank J. Kelley.

THE ALLEY GLASS CO., Shinnston, W. Va., has been incorporated with a capital of $10,000, to manufacture glass products. The incorporators are L. E. Alley, and Paul E. Tetrick.

THE MILTON A. EDGAR CO., Metuchen, N. J., has been incorporated with a capital of $50,000, to operate clay properties. The incorporators are N. G. Edgar, M. A. Rick and Milton A. Edgar, 115 Lake Ave., Metuchen.

THE JOY CHEMICAL CORP., Brooklyn, N. Y., represented by H. A. Eberhardt, 92 William St., New York, has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are Earl G. Hart, Jr., H. J. Cluskley and C. B. Brucker.

THE CLINCHFIELD SAND & FELDSPAR CORP., Bristol, Va., has been incorporated with a capital of $600,000, to operate feldspar properties for the production of commercial feldspar. Henry N. Hanna, 296 Water St., Baltimore, Md., is president, and George M. Warren, Bristol, Va., secretary.

THE DYESTUFF & CHEMICAL CO., Wilmington, Del., has been chartered under state laws, with a capital of $25,000, to manufacture chemicals, chemical byproducts, dyestuffs, etc. The incorporators are Walter A. Ryan, H. G. Stevens and George C. Hering, Jr., all of Wilmington. The last noted represents the company.

THE C. E. BECKMAN CO., New Bedford, Mass., has been incorporated with a capital of $100,000, to manufacture oils, paints, etc. Charles E. Beckman, 243 Arnold St., New Bedford, Mass., is president and treasurer.

THE STEVENS PAPER CO., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture paper products. The incorporators are R. L. Stevens, Jr., R. A. Smith, J. S. Beach and G. R. Williams, 165 Broadway, New York. The last noted represents the company

THE CARL FISCHER TIRE & RUBBER CO., 1414 South Michigan Ave., Chicago, Ill., has been chartered under state laws, to manufacture tires and other rubber goods. The incorporators are Carl R. Fischer, Francis A. Winship and John C. Dewolf.

THE COLONIAL CONCRETE PRODUCTS CO., 111 Collins Ave., Baltimore, Md., has been incorporated with a capital of $60,000, to manufacture concrete blocks, and other cement products. The incorporators are George L. Jones and J. R. Carroll.

THE UNITED CHEMICAL & INDUSTRIAL CORP., Baltimore, Md., care of J. Bannister Hall, Jr., Calvert Bldg., has been incorporated with a capital of 30,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts.

THE TRIPLE REFLECTOR CORP., Philadelphia, Pa., care of the Corporation Guarantee & Trust Co., Land Title Bldg., has been incorporated under Delaware laws, with a capital of $100,000, to manufacture glass products.

LORIO SUGARS, INC., Lakeland, Fla., has been incorporated with a capital of $25,000, to operate a local sugar refinery. A. A. Lorio is president; L. F. Lorio, vice-president; and W. A. Lorio, secretary and treasurer, all of Lakeland.

THE RIVERTON MILLS, CORP., Riverton, Va., has been incorporated with a capital of $40,000, to manufacture commercial fertilizer products. B. J. Hillidge is president; and W. J. Dearing is secretary, both of Front Royal, Va.

THE HEINZERLING OIL CORP., Vernon, Tex., has been incorporated with a capital of $30,000, to manufacture petroleum products. The incorporators are J. B. Brady, and W. H. Heinzerling, both of Vernon.

THE STATES RUBBER & SUPPLY CO., 227 West Randolph St., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture rubber specialties. The incorporators are Arthur Cordell and Michael C. Yunker.

THE PETERSON PATENT LEATHER CO., Woburn, Mass., has been incorporated with a capital of $6,000, to manufacture leather products. Brunswick G. Fowler is president; and Alfred W. Peterson, 61 Bow St., Woburn, treasurer.

THE BAKER REFINING & MFG. CO., Jacksonville, Fla., has been incorporated with a capital of $10,000, to manufacture oils. H. Baker, Jr., is president; J. T. Meyers, vice-president; and H. T. Miller, secretary, all of Jacksonville.

THE NON-PUNCTURE TIRE CO., Binghamton, N. Y., care of Mangan & Mangan, Binghamton, has been incorporated with a capital of $50,000, to manufacture tires and other rubber products. The incorporators are G. A. Reynolds, Sr. and Jr.; and F. H. Wilbur.

THE O'BANNON AIRLESS TIRE CORP., New York, N. Y., care of Woodburn Martin, Georgetown, Del., representative, has been incorporated under Delaware laws with a capital of $250,000, to manufacture tires and other rubber products. The incorporators are J. V. Pacher, A. J. Pratting and E. H. Klinglefus, all of New York.

Industrial Notes

THE TITAN IRON & STEEL CO., INC., Newark, N. J., manufacturing mechanically puddled wrought iron, has announced the appointment of W. Woodward Williams as vice-president. Mr. Williams' long experience in the iron and steel industry began immediately upon his graduation from Harvard University in 1905. After 6 years in the mills of the Carnegie Steel Co. at Pittsburgh, Duquesne and Youngstown, Mr. Williams entered the sales department of the Bourne-Fuller Co. of Cleveland and was later appointed manager of its Pittsburgh office. In January, 1914, he became general manager of sales of the A. M. Byers Co., Pittsburgh, and subsequently was made its general manager. In August, 1919, he became general manager of the Reading Iron Co., and afterward was elected vice-president, in charge of sales and operations. In September, 1920, he became associated with the Pittsburgh Gage & Supply Co., jobber of wrought iron merchant pipe in the United States, resigning the vice-presidency on May 31, 1922, to take the vice-presidency of the Titan Iron & Steel Co., Inc.

THE ZELLER MFG. CO. has announced, through Mr. Hugo Zeller, that, contrary to recent trade rumors, there is no connection between the organization and any other company manufacturing lacquer. The Zellers at one time were actively and financially interested in the Egyptian Lacquer Mfg. Co., but since the Zeller Lacquer Mfg. Co. was formed, the Zellers sold out their interest in the Egyptian company so that there is now no connection whatsoever between the two concerns.

THE CHICKASAW REFINING CO., Ardmore, Okla., at a recent meeting of stockholders elected S. A. Apple as president. Other officers elected were: Erret Dunlap and Perry D. Maxwell, vice-presidents; F. A. Schneider, secretary-treasurer; and John Holt, assistant secretary-treasurer.

THE IRON PRODUCTS CORP., New York, and its subsidiaries, the Central Foundry Co., the Central Iron & Coal Co., the Central Radiator Co. and the Molby Boiler Co., announce the opening of a district sales office in the Jefferson County Bank Bldg., at Birmingham, Ala., June 1, 1922. T. C. Hyde will be manager of the new office, under the direction of J. L. Brierton, vice-president and general manager of the Central Iron & Coal Co.

Manufacturers' Catalogs

THE CRESCENT PUMP CO., Detroit, Mich., has issued Bulletin 5, on Crescent "Roto-Piston" dry vacuum pumps. This 12-page booklet illustrates and describes the pumps, tells of the movement, details of foundation, guarantee and a list of the applications for vacuum.

THE THWING INSTRUMENT CO., Philadelphia, Pa., has issued Bulletin 11, which illustrates and describes the company's complete line of indicating and recording radiation pyrometers.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold a summer excursion meeting to Rochester, Montreal, Ottawa, Kingston, Toronto, Hamilton, Niagara Falls and Buffalo, Aug. 13-19.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition at Atlantic City, Oct. 23 to 28.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer, but will resume them in October.

Senate Rejects Dye Embargo

MUCH to the surprise of all interested in the dye and chemical industries of the United States, the Senate last week voted to eliminate from the tariff bill the item extending the embargo on dyes for a period of one year after the bill becomes law. It is quite evident that in taking this action the Senate was influenced by the Government's proceedings against the Chemical Foundation for the return of the German dye and drug patents sold by the Alien Property Custodian. Friends of the dye embargo were fearful that the Government's action would confuse the embargo issue in the minds of some senators and thus unfavorably affect the safety of that measure.

These fears proved to be only too true, for the vote on the embargo was preceded by violent attacks on the Chemical Foundation and the whole chemical industry. Senators Moses and King led the assault. It would be difficult to listen to Senator Moses and refrain from levity if the issue were not so momentous. He was alliterative but not convincing. He has long been the loyal servant in the Senate of the Amoskeag mills in New Hampshire and has consistently opposed the establishing of a dye industry in this country. As for Senator King, he was so thoroughly discredited in the dye investigation that he carries no weight.

But the fight is not over and the day is not yet lost. Senator Frelinghuysen announced that he would demand another vote on the proposal when the bill is considered in the Senate proper and not as committee of the whole. In the meantime it behooves all friends of the dye industry to see that their senators are under no misapprehension of the necessity for an embargo and are not confused by the proceedings of the Government against the Chemical Foundation.

The Public's Interest in Settling the Coal Strike

AS IN THE CASE of practically all labor troubles, there are three parties involved in the coal strike —the miner, the operator and the coal consumer. The President's proposed plan of orderly settlement is eminently fair in that it looks primarily to the interest of the public. To set up an impartial tribunal to pass on the issues of a controversy in which workers and employers have failed to reach an agreement on their own initiative is assuredly in line with the best thought and sober judgment of the day. To capitulate to the demands of such an all-powerful and unreasoning force as the United Mine Workers would be a sacrifice of principles to which we cannot agree. Equally undesirable would be a surrender to any plan of the mine owner which does not offer a solution of the fundamental economic problems that underlie the coal industry.

The ranks of both miner and operator, if we see the situation rightly, are too close to the battle to get the broad perspective that is really needed. In concentrating their attention on the immediate difficulties and detailed problems arising out of the President's plan, they fail to appreciate the inherent possibility which this sort of settlement promises to their industry.

Before considering the public's interest in the coal strike, however, let us briefly review the operators' and miners' reaction to the plan. At first both seemed to be willing to accept the proposal "in principle," but at the same time were looking madly about in hopes of finding some means that would lead to its ultimate rejection. Finally, the miners took the responsibility of opposing public opinion by refusing to arbitrate. This was the cue for the operators to join with the public in piling high the blame on the other fellow and thoroughly punishing him for obstructing progress.

The operators see in the plan a victory for the unions, because the "uneconomic" wage scale, against which they have fought for almost four months, is now to be extended until August 10, and perhaps until March 1, 1923. In the opinion of *Coal Age* this is "to surrender to the campaign of intimidation, terrorism and massacre that has characterized the union's conduct in this strike." The labor officials' first reaction to the proposal was to question the motives of any possible representation of the public on the President's commission—apparently on the assumption that they will not receive fair treatment in the hands of any disinterested party. Such a stand is so obviously greedy as to be universally deprecated. The miners also appear to be opposed to the setting up of any agency such as the Railroad Labor Board, with power to handle wage rates permanently and to enforce their decisions. Such a plan may not be contemplated by the President, but there are those among the public who are inclined to regard it as a lasting solution for the bickering and bargaining that causes the constantly recurring labor difficulties in the coal industry. Furthermore, the miners insist that the recommendations of the commission apply to operators in all sections of the country, thus reopening the issue in partially unionized fields, where war-time wage scales have already been broken down.

The thing that the public is most interested in is a dependable supply of fuel produced by an efficient and properly functioning coal industry. The public will have none of the purely partisan demands of the operator and miner. As George Otis Smith has aptly said, "The people's coal costs too much because of the mistaken idea that mine owner and mine worker can continue indefinitely to fight over wages and rules. Cheaper coal and larger earnings will come when engineering is emphasized more and bargaining less. In terms of engineering, the coal industry has a bad load factor; translated into human relations, poorly func-

tioning mines mean poorly employed miners. This over-developed industry must suffer deflation; fewer mines can and should furnish the needed coal." In other words, the public wants to see this industry put on a fundamentally sound economic basis. If the President's impartial investigational commission can make recommendations that will ultimately result in the "establishment and maintenance of industrial peace in the coal industry and the elimination of waste due to intermittency and instability," then will the interest of the public have been adequately and honestly served.

One of the Black Arts

"WERE IT NOT to be considered sarcasm, this industry might even be referred to as a 'black art,' first because of the usual secrecy regarding its processes and second, because of absolute dirtiness of the average electrode plant. Carbon works are generally regarded as fortifications through whose gates only the initiated may enter." This is the indictment one of our authors makes of a large and basically important chemical industry. This generalization, we are happy to record, is not universally true even in the electrode industry for we know some manufacturers whose works are always open to the technical public. And curiously enough, these are the plants in which the greatest progress in technology has been made.

Nevertheless one need but search through the very meager literature on electrode manufacture to realize how slow has been the spread of technical information in this industry. For this reason, if for no other, it is with some little pride that we direct our readers' attention to the important series of articles on the technology of the carbon-electrode industry which will be published by this magazine. The first of the series, appearing on pages 109-12 of this issue, is an account of the remarkable development of electrode manufacture. Rarely have we had the pleasure of publishing such an interesting bit of technical history. Were we searching for another explanation of the "black-art" characterization of the electrode industry, we would need go no further than to call attention to its almost magic development.

It is a long cry from 1800 and the little black rods of carbonized wood with which SIR HUMPHRY DAVY struck the first electric arc, to 1921 and the National Carbon's mammoth furnace electrode, 15 ft. long, 20 in. in diameter and weighing over a ton and a half. But 120 years is a comparatively long time when it is realized that in our own country in less than one-fifth of that time our output of electric-furnace electrodes has increased in value from $10,974 (in 1899) to well over $10,000,000 (in 1921). And were we to include electric-furnace products in that comparison the figures would be almost unbelievable!

To the Frenchman, CARRÉ, belongs the credit in 1876 for the first commercial manufacture of carbons. But he was followed closely by several Americans: DAVID THOMPSON of Newark, N. J., was probably the first American producer and it was CHARLES F. BRUSH of Cleveland who molded the first electrodes from petroleum coke and thus laid the real foundation of the industry. Brush, too, devised the calcination process and was the first to use really high pressure in molding and later in the interesting extrusion or "squirting" process of making electrodes. As the electric-furnace developments of SIEMENS, HEROULT, ACHESON and HALL took root in this country and grew so tremendously, the carbon industry was called on to supply an ever increasing volume of its products. With this demand came the need for gigantic electrodes capable of standing up under terrific service in the huge electric furnaces for making carbide, ferro-alloys and steel. And following this progress came the astounding evolution of the industry during the war. On the basis of such a record it is difficult even to hazard a guess as to the limits the industry may reach in the future.

Since the days of CARRÉ and SIEMENS, electrode manufacture has been practically revolutionized by the introduction of modern labor-saving machinery. Much of the progress of the industry is doubtless attributable to the use of large-scale and scientifically controlled equipment. It is believed, therefore, that more than usual interest will attach to the succeeding articles of this series, most of which are intimately concerned with the design and operation of equipment used in the calcining, molding, extrusion and baking processes. In offering these articles to our readers it is with the hope that they will arouse the sort of criticism and comment that will ultimately benefit the carbon industry. Only through the free interchange of information regarding its fundamental technology can this industry dispell the gloom of mysticism and secrecy which has characterized its past.

Are You Guilty of Meticulous Precision?

WE WERE fortunate enough to study quantitative analysis under a professor who invariably did the following thing: If an analysis were reported as 7.0125 per cent and the accuracy of the analysis allowed only two decimal places, the professor marked the result wrong. Many a young and enthusiastic analyst protested vigorously at this summary treatment, but by that same token many a young and enthusiastic analyst learned a lesson which he never forgot and so, too, did the rest of the class. $2 + 2 = 4$ and not 4.0000. But analysts are not alone in falling into this error. Engineers are notorious offenders.

We recall one instance where a celebrated engineer was preparing a set of tables for publication and was using a set of twelve-place logarithms. We asked why he used twelve-place tables and he replied that they were the best he could find, that he had heard there were twenty-place tables but he had been unable to locate them. The interesting thing about this anecdote is that practically all the data which the celebrated engineer was tabulating had an accuracy which was seldom better than 1 per cent and an ordinary 12-in. slide-rule would have been amply accurate for the work.

Again, when a young engineer is about to make a mathematical calculation, say for example the surface of heating coils necessary to obtain certain results, he will almost invariably sit down and calculate it to an accuracy of a tenth or even a hundredth of 1 per cent and this in spite of the fact that the constant factor in the equation (the rate of heat transfer) may not be known within 50 per cent.

Herein lies one excellent reason why many a practical man with good common sense and a wide experience has been able to compete with engineers in many fields. The engineer frequently has technical training only with no balance wheel of common sense that would te

im that a given result, although mathematically correct, is logically absurd.

We have attended conferences and conventions on ngineering education and have heard some studies haracterized as a waste of time for an engineer taking four-year course. Yet we always wonder if that very ourse in some institution may not be the one to give ne student the balance he needs almost more than anyning else in his technical work. Perhaps the professor ho gives that particular course is the one who would est accomplish that much-to-be-desired result. hrough every phase of the chemical field and through lmost every profession we find the need of a sense of alance and proportion, the ability to stand off and ook with perspective at a given problem and say, Here and here are the important things, the rest are iphers beyond the limit of accuracy of the problem." nd so whenever we come in contact with some lack f balance, on the part of technical men in particular, e bless the professor of quantitative analysis who narked us wrong when we said that 2 + 2 = 4.0000.

Turning Accident Into Disaster

TWO WEEKS AGO the City of New York was shocked by an accident in its subway system resulting from the use of pyrene, a carbon tetrachloride re extinguisher, in an attempt to extinguish an electric rc. About 150 men and women were overcome by he resulting fumes and the city's fire and police departments were summoned to the rescue. Some of the assengers were seriously affected and confined to the ospital although most of them soon recovered from heir involuntary "gassing."

The incident is one of special interest to chemists nd technical men because it furnishes another example f the direct relation of chemistry to the public welfare. he resulting investigation has shown what was already ommon technical knowledge, namely, that carbon tetrahloride sprayed on heated surfaces in a small enclosure ives rise to fumes of phosgene and sometimes chlorine nd hydrochloric acid. The unfortunate feature of the ffair was that a slight accident resulting from a short ircuit in a switch box, which need not have had serious onsequences, was turned into a near tragedy by the gnorant use of a fire extinguisher with which subway ars never should have been equipped.

Accidents of this kind always emphasize the great roblem of widely disseminating the knowledge that is eld by specialists and which is available for the public f it knew where to seek it. The U. S. Bureau of Mines, or example, has long since investigated carbon tetrahloride fire extinguishers and has made known in a echnical paper by Fieldner, Katz and Kinney, all of he facts necessary to forestall the use of such devices n subway trains. But how shall the results of such nvestigations, duly recorded in a government publication, be given the wide publicity they deserve? It may e said to the credit of the Transit Commission that ts investigation led it to call upon the Bureau of Mines or advice, but apparently no one thought of seeking t before the accident demanded it. One cannot help eeling that the manufacturers owed a duty to the ublic which would have led them to refuse to sell a ire extinguisher of this kind for use where it could ave such terrible consequences. An order has since een issued to discontinue the use of pyrene in subway ars, but there are still millions of people in the country who may suffer a distressing and even fatal accident if they are not informed on the proper use of carbon tetrachloride in putting out fires. It should not be used in small enclosures. Chemists generally can be of great service in spreading this information.

Science and The Daily Press

SOMETIME ago the Washington *Star* published under the caption "Faith in Science" an editorial that was most encouraging because it indicated a truer appreciation of science on the part of the daily press. It led us to believe that the day is approaching when we can expect to read in our daily newspapers reliable and trustworthy items on scientific progress instead of the scare-head stuff that still seems to meet newspaper standards and ideals. The editorial in question related how once it was "the fashion to class all researchers and inventors with the perpetual motion cranks." But it went on to show the change that is taking place in the public's appreciation of science, as a result of which research and invention are now accorded the dignity they deserve.

This is fine as an editorial expression but it would be finer still if it found practical application in a censorship of the contents of newspapers. The daily press is, and for many years will continue to be, the great medium of publicity through which the public can get a general impression of science and technology. This entails a duty which is far from being performed and a responsibility which has not yet been met. While we have occasional evidence of editorial sanity as indicated in the Washington *Star*, news columns are still filled with alleged scientific stories that are played up by the energetic reporter with a nose for news. In other words, the standards avowed on the editorial page find no expression in the news columns, which, incidentally, is one of the most radical differences between the daily and the technical press.

As yet the newspaper editor makes no discrimination between the announcement of a discovery or invention by an Einstein or a Marconi, and a nondescript screed on the alleged discovery of "life crystals" by Mrs. Maud Dickinson of Brighton, England, hitherto unknown to fame. Columns are devoted to her alleged discoveries because they are shrouded in mystery and because she has been bold enough, or foolish enough, to announce that perhaps she has discovered "the source of all life." Perhaps! Certainly she has discovered a great source of publicity. She talks of "a self-created scarab or beetle of old Egypt" which in some marvelous manner "formed crystals outside and away from the bottle in which it was kept." It staggers the imagination to think what the scarab might accomplish if turned loose instead of being kept in close confinement. It is reported further that "the discovery was made by accident." We can believe it. Why not investigate the accident and find out what really happened instead of leaving our minds confused with vague references suggestive of alchemy, mythology or clairvoyance.

The daily press has a greater responsibility than it realizes in passing out this kind of scientific bunkum to the people. In many respects daily journalism is on a high plane, but its editors have not yet learned to throw such stuff into the waste basket.

Readers' Views and Comments

Effects of Impurities on Electrolytic Zinc

To the Editor of Chemical & Metallurgical Engineering

SIR:—Dr. Scholl's data presented in his paper "Effects of Impurities on Electrolytic Zinc," in *Chemical & Metallurgical Engineering* for March 29, 1922 (vol. 26, p. 595), reasonably confirm the data already published by a number of investigators of this same question.

His photographs, however, appear to me to indicate that his observations were complicated by "doped" solutions—i.e., solutions containing glue or something analogous to it. The striations shown are, I think, invariably due to hydrogen liberated at the cathode and rising through the solution along the cathode surface. Liberation of hydrogen in quantity bespeaks low current efficiency, so, in one way, it is legitimate to refer the striations to the causative impurities.

The various protuberances, "warts," "trees," "sprouts"—whatever you may care to call them—which, as Dr. Scholl's photographs show, become more strongly marked as deposition goes on, can be more readily produced by adding glue-like materials to solution than by any other method I know of. It is my own impression that they are more nearly a characteristic of the "addition agent" and of the quantity of "addition agent" added than they are of specific inorganic solution impurities.

Impurities Accelerate Efficiency Drop

In my own experience, the current efficiency of a zinc cell invariably falls off as deposition goes on (everything else—acidity, temperature, etc.—being kept constant). In pure electrolytes the initial current efficiency is high and the rate of decrease nominal. In impure solutions the initial current efficiency may be fairly high, but the rate of decrease is also high—i.e., I doubt that with certain impurities one does get normally high current efficiencies over a period of several hours and then a sudden inversion when all other factors affecting deposition are rigidly kept constant.

Glue and other glue-like addition agents are oxidized in the cell—i.e., glue concentration changes continuously within a closed cell circuit. I do not understand the action of the glue in spite of much that has been written concerning its action, but I have seen such apparent inversions of current efficiency as Dr. Scholl reports and still it has seemed to me that I could always find some reason for a sudden inversion that did not inhere in the impurity *per se*.

Of the papers concerning the effects of impurities upon zinc deposition that have been published so far, the one that has seemed to me to most nearly correlate observed data is that by Tainton (American Electrochemical Society *Transactions*, 1922). Tainton attributes the effects of impurities to the relative overvoltages for hydrogen of the impurities and of zinc. Zinc, of course, could not be deposited from aqueous solutions were it not that zinc does so strenuously object to having hydrogen deposited at its surface.

I know of but one or two observations that indicate need for something more in the way of explanation than the overvoltage theory, and it may readily be that these can be shown to be incorrect observations.

Iron has about the same overvoltage as cobalt and nickel. The zinc cell is not nearly so sensitive to the presence of iron in solution as it is to the presence of cobalt or nickel.

Solutions containing manganese are particularly sensitive to antimony and only slightly less sensitive to arsenic. If these solutions are treated with permanganates in such manner as to remove all manganese, the arsenic and antimony are usually also eliminated—particularly if ferric salts are precipitated. Solutions so treated yield zinc at maximum current efficiencies, and these solutions are relatively insensitive to the addition of arsenic and antimony. I have electrolyzed such solutions after addition of 17 parts of antimony per million, and, if I remember correctly, Mr. Lee at Trail told me he had added the better part a gram of arsenic per liter (1,000 parts per million) to similarly treated solutions, and yet these solutions yielded zinc at very high current efficiencies.

Unfortunately, one's conclusions from given experimental results are subject to change as an art develops, and I think much of our present perplexity might be set aside by repeating early experiments and interpreting the results in the light of more recently acquired knowledge.

New Vogue in German Dyes for Socks

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have just returned from Wonderland. I never appreciated before just how wonderful a country it is. Before leaving these shores of Bungle Land, I had become thoroughly convinced that since *der Wacht* no longer *fest steht und treu* on the Rhine, the dyes of Wonderland constituted the one peerless example of permanency in this world of "relatively" changeable things. Of course, this is so. But the dye chemists of Wonderland have improved on permanency. Of course, to observe all the rules of testimony, witness should be duly sworn and submit his exhibits. The exhibits, however, in this case are my feet, and since *Chemical & Metallurgical Engineering* does not publish multi-colored plates, witness will simply have to depose that having bought a number of otherwise very excellent socks in Germany, his feet are now dyed a beautiful brilliant green.

It is obvious that this is a great improvement in socks and is doubtless fully protected by a Deutsches Reich Patent. Some people would prefer perhaps to have pink toes but this can doubtless be arranged with the master dye-makers of Wonderland. In my case the result, while perhaps not *kolossal*, is at least *tadelos und wunderschoen*. Probably the inventor of this improvement got his idea from the dyed papers with which in former years we used to transfer wonderful dyed patterns to Easter eggs. Nevertheless, it is a great idea and I felt that I should mention it to show how far behind times our dye chemists of Bungle Land really are.

Article V in This Series and the First Article on Accounting—The Calculation of Chemical Efficiency or Yield in Different Types of Chemical Plants—Errors in Plant Accounting Methods

The Business Side of Chemical Manufacturing

By Charles Wadsworth 3d

THERE OUGHT to be a fable about a man who felt so keenly the importance of the subject about which he was going to talk or write that he choked to death trying to enunciate some superlatives which would, in his estimation, be adequate to the situation. If there were such a fable, I should invoke it at this time. The importance of accounting in chemical manufacturing is so great, so vital and so essential to the success of any one unit, that there are not enough superlatives to make the point sufficiently impressive.

Couple with this the fact that technical men in chemical manufacturing industries are almost completely ignorant of accounting and that even the chemical executives and manufacturers do not possess a wide knowledge of the application of accounting principles to manufacturing problems nor any understanding of the interpretation of accounts. All these things contribute in making any one familiar with the benefits which accrue from the application of accurate accounting to manufacturing industries adopt the attitude of an irate pedagogue towards an unusually stupid and recalcitrant pupil.

In these brief articles, we hope only to emphasize the importance of accounting to chemical industries and to point out a few of the weaknesses of existing systems. Turn your attention to the accounting department and to accounting methods whether you are an executive or an analyst. Look at the forms that are used and discover for yourself how accurate the present system is and to what variations it is subject. This article will discuss plant accounting and the last article in the series deals with costs and cost finding systems. When you realize that less than five per cent of the business houses in this country have cost systems, the truth of the often-quoted statement is brought home to you: "It would be better for most business houses in this country to shut up shop and throw dice for a living—their chances of success would be greatly improved."

Chemical Plant Accounting

Are Accurate Production Efficiency Figures Important?

An accurate production efficiency or, as it is more generally called, yield figure, is the pulse of a chemical plant. It would seem to be pretty obvious that an inaccurate yield figure is worse than useless, because it is misleading. It is strange that it should be necessary to point out this rather fundamental truth and yet company after company gives allegiance to a system which cannot produce accurate yield figures. We will take up, a little later on, some of the errors which invalidate yield calculations and estimates.

A true manufacturing yield should and can accomplish three things. It will reveal the chemical efficiency of the process in question. Further, in revealing this efficiency, it will open the way toward improving it. Finally, it will give a reliable line on the work of the manufacturing man. Too often it is impossible now to answer the question, "How well is Jones doing with such and such a unit?" These benefits all have to do with the manufacturing unit itself and do not take up the consideration of the rest of the organization. In addition, true manufacturing yields form a basis of accurate costs and accurate costs are the criteria upon which executive decision must be based. It will be seen then that the cornerstone of intelligent executive action lies in an accurate and workable system of plant accounting.

What Do You Mean—Plant Account?

So far as can be summarized briefly, plant accounts should give consumption of raw materials, production of finished products and the efficiency obtained in the process. Obviously, different kinds of chemical processes require different accounting systems. In the first place, there are to be differentiated small batch processes as distinguished from large scale or continuous processes. It must be apparent that the accounting system for a batch process will in general be simpler than that of a continuous process. With a continuous process there will be no definite point at which you can say, this much product came from that much raw material. There will always be material going in to be consumed and there will be a somewhat indeterminate quantity of material in process. Allowances must duly be made for this condition.

This is only one of a large number of groups into which chemical plants may be divided. Each separate group will need a different accounting system and the number of different systems becomes legion. We shall try to develop some typical examples of methods of recording data and calculating yields, indicating the changes which are necessary when complications arise in the type of process.

There are a good many ways of expressing plant yield or efficiency. The most scientific method of course is to calculate the theoretical yield which should be obtained from a given amount of raw material and divide this into the amount actually obtained. The quotient, with proper decimal point, is the per cent of theoretical or ideal efficiency. This figure is an absolute as well as a comparative figure.

In many firms you will find a peculiar survival in use. Two hundred and fifty per cent yield! How would that appeal to you? Unfortunately, all that it means is that pound for pound you get a quantity of product equal to $2\frac{1}{2}$ times the original weight of one of the raw materials. It is an entirely empirical figure and the actual weight produced per day would be just as good, assuming you consumed a consistent amount of raw material. It does serve as a comparative figure however from one month to the next.

Expressed in lowest terms then we must know how much material goes into a process and how much prod-

uct comes out. These, with the elementary chemical equation, are all that it is necessary to know to calculate yield.

A Few Complications in Yield Calculations

When two or more raw materials are used in manufacturing the same product, there arises some complication as to which shall be used as a basis on which to calculate the yield. For example, sulphuric acid and salt are both used in making hydrochloric acid. The yield based upon the salt used will not be the same as that referred to sulphuric acid. In such a quandary, it is a frequent practice to refer the yield to the most expensive raw material. This in turn is usually the material which is not used in excess, but from which you should get a definite and molecular quantity of product. In some cases the most expensive raw material is used in excess and in such cases it is more usual to calculate on the basis of the material which is used in the proper proportion to produce molecular quantities of the product.

Still another complication arises when two or more products are produced from the same raw material. Our illustration used above still applies, for both sodium sulphate and hydrochloric acid are produced at the same time from sulphuric acid and salt. Now the yields of sodium sulphate based on sulphuric acid or on common salt will differ from each other and also from those yields based on the production of hydrochloric acid. In order to calculate the efficiency of the process, it is usually customary to take the more desirable product and refer it to the raw material used in molecular quantities and not in excess.

Again, in some chemical reactions, one product is made at the expense of another product as in the case of the di-substituted aromatic organic compounds when both ortho and para are formed in varying amounts, depending on conditions. Here, assuming we want paranitrophenol instead of orthonitrophenol, the yield would be expressed in terms of the para product referred to the nitrophenol equivalent of the phenol used.

The case of expressed oils or extraction processes is not infrequently met in chemical processes. It is difficult to obtain a representative sample of the raw material and this is particularly true when the material is of vegetable origin and a certain amount of soluble material is to be extracted or pressed from the crude. If we take a sample of copra, for example, it is a difficult matter to obtain a laboratory figure which will represent accurately its coconut oil content. This is due to a number of things, the greatest of which is the mechanical difficulty of sampling tons of material accurately and putting it into an extraction thimble in the laboratory. Thus we would be able to weigh the copra and to obtain accurate samples and weights of the expressed coconut oil, but we would not know accurately what per cent of the oil was extracted in the process.

Finally, there are processes such as the fractional distillation of petroleum or coal tar, in which an ordinarily expressed yield is not significant since the products are so numerous. Plants such as those for making portland cement in which the finished slag is never weighed nor estimated accurately present another difficulty. In these cases a yield is not significant at all, except over a period of, say six months or better still, a year. Then a rough estimate of the slag pile can be made and the quantity in the slag pile will perhaps represent only a small per cent of the total production, whereas over a shorter period of time the variations in estimating this slag pile would be so great as to vitiate any yield results at all.

Simplest Type of Plant Account

The Small Batch Process

For purposes of illustration we shall take an entirely fictitious process—the formation of glaubers salt from caustic soda and sulphuric acid. Let us assume first that we are to produce 500 lb. a day. This is analagous to hundreds of processes in use now for the production of fine chemicals. In making 500 lb. of glaubers salt, we would use 127 lb. of caustic soda (76 per cent Na_2O) and 163 lb. of oil of vitriol (93 per cent H_2SO_4). In using such small quantities of material, it is customary and safe to trust the daily weights which go into the process. The materials used on this scale are usually expensive and the operating system is so arranged that variations in weight of the raw materials are slight and easily checked. In this type of process it is not infrequently the custom for the purchasing agent to be responsible for stocks of material. They are used in such small quantities that the daily increment is only a small part of any given shipment. The date for replenishing stock can, therefore, be plotted with periodic regularity. The accounting data required from this type of plant are few. They may be recorded with a great many operating data, but we are not at present concerned with these. Below is printed a sample form which might be used in this glaubers salt process.

1. Weight caustic soda (76% Na_2O) used.....
2. Weight oil vitriol (93% H_2SO_4) used.....
3. Theoretical quantity glaubers salt obtained from caustic soda used.....
4. Actual quantity obtained.....
5. Plant Efficiency or Yield $\left(\frac{\text{No. 4}}{\text{No. 3}}\right)$ .....

An analysis of raw materials is necessary in a small plant such as the one we are describing if only to check up the purchasing specifications. No rigid system or form should be necessary for reporting the analysis. There is great danger in small plants of running system into the ground and of having rigidly prescibed procedure for situations that do not happen more often than once a quarter or once a year. If the plant becomes larger and the units increase in number it is necessary to have a rigid system for reporting analysis of raw materials and even for getting samples of these raw materials. It also becomes necessary then for the operating men to take care of the stocks on hand and requisition the purchasing department in time to replenish them. All these things are operating details but have considerable bearing on accounting, due to the fact that plant yield and cost must be calculated on a basis of these operating reports.

From this simplest form of plant account there develops all degrees of complication in methods. We shall discuss in detail next a complicated system used in large batch processes or continuous processes. It will be impossible to take up all the necessary forms and we have therefore printed a fac-simile of the general summary of plant-yield indicating such supple-

mentary forms as are customary. The gaps between these two types can be interpolated with the help of the general principle—"Don't put in a single form that isn't essential. If you can do without it, *do!*"

Effect of Increasing the Size of the Plant Upon Accounting Methods

Instead of making 500 lb. of glaubers salt per day, imagine the plant turning out 50,000 lb. per day, or 25 tons. Obviously the consumption of 12,700 lb. of caustic soda and of 16,300 lb. of sulphuric acid is a very different mechanical problem from 127 lb. and 163 lb. In the first place, although the raw material is invariably weighed or measured in some way as it goes into the process, there will inevitably be inaccuracies in such figures in plants of this magnitude because of the low intelligence of the labor ordinarily employed in operating work. Yield figures cannot be calculated from the process weight and hence we cannot obtain a yield figure from a daily batch unless we check that figure by estimating the stock of materials on hand and calculating from these the consumption during the day. This would be entirely out of the question because of the expense involved and therefore, it is usual to take a given period, say a week or fortnight or even a month, and to calculate the stock of materials on hand at the beginning and at the end of the period. Then the consumption of raw material is equal to the stock on hand at the beginning of the period, plus the receipts of raw material in the plant, minus the stock on hand at the end of the period.

It is obvious, of course, that with a plant of this size a very much larger stock of material must be kept on hand than in the first case. A month's supply would be 381,000 lb. of caustic soda and 489,000 lb. of oil of vitriol. It is a comparatively simple matter to estimate the stock of material on hand with great accuracy when the goods are in packages or containers of fairly standard weight, or when the material is a liquid and stored in tanks. When, however, you are dealing with bulk material in piles or bins the estimate is not nearly so accurate. Errors in estimating stock of bulk material are of two kinds. In the first place, it may be due to an inaccuracy in estimating the cubical content of the pile and in the second place, it may be due to employing a wrong specific weight factor. If two separate measurements on a pile of coal or brimstone check within 1 per cent, the measurers may call it a day. It is just about as close as can be averaged on successive checks. Closer checks are often the brag of various plants and organizations, but they are hardly ever consistently closer. It is a very easy matter indeed to miss a measurement by a few inches and obtain a startlingly different result. Thirty-five per cent variation is not an uncommon experience although when rechecked, one of the measurements will be found to be grossly in error.

The second error arises from the use of inaccurate specific weight factors (the weight of a cubic foot) with which to convert cubical content of piles into weight. Variations in this factor are often due to the fact that material packed in piles is not nearly so densely crowded at the top as at the bottom. Frequently too, raw material from different sources has a different specific weight and due to a somewhat inflexible system, this is overlooked in many factories. Other factors, such as moisture content, frequently affect the packing of the material. The product of our fictitious plant, glaubers salt, is an example of this. It is usually stored in bins as wet crystals without any drying. Actual contents of a given bin vary greatly and only a rough approximation of the stock of materials can be made.

Correction for Stocks in Operation

Whenever the amount of material tied up in manufacturing becomes an appreciable per cent of the production during the given period it must be corrected for. In other words, the stock of material at the beginning of the period may not be the same as the stock of material in operation at the end of the period. Obviously this would have an effect on the consumption of raw material and consequently on the plant yield. This is a nuisance to the plant men and therefore, unless the system is sufficiently rigid and carefully supervised, the results are likely to be quite inaccurate.

The yield records in this type of plant are considerably more involved. The insert gives a log sheet of our fictitious plant for producing 25 tons of glaubers salt per day.

In addition to the form shown, which acts as a summary, it is necessary to have a detailed report on the stock of raw materials and finished product and the quantity of materials in operation. This requires an itemized summary of the material in every piece of equipment together with some chemical analysis or density measurement to translate volume into weight. In some plants this can be combined with the above report.

PRODUCTION OF GLAUBERS SALT

Period ending.....

CONSUMPTION OF RAW MATERIALS

Caustic Soda		Oil of Vitriol	
Stock last report		Stock last report	
Shipments received		Shipments received	
Total (A)		Total (E)	
Stock on hand		Stock on hand	
No. of drums		Tank 1 ..... in.=	lb.
Average weight		Tank 2 ..... in.=	lb.

Total (M)	
Stock on hand (beginning of period)	
Materials in operation (beginning of period)	
Total (N)	
P. Production (M-N)	

YIELD

R. Theoretical production from caustic soda consumed	
Yield (Efficiency) P/R	

In taking an inventory in this type of plant the volume, density and chemical analysis of each container must be obtained. Sometimes the analysis can be reduced to a specific gravity determination with proper allowance for temperature. I should have written the last four words in capitals, for there are a great many plants that disregard this completely, curious though it may seem and their actual results are thrown out by as much as 5 to 10 per cent on this account in some instances.

Still another rather foolishly obvious precaution is that the chemical condition of the material in operation should be considered, yet many a time an estimate of material in operation is made as though it were all raw material and not part changed to the product. All these things have their effect on the ultimate yield.

With such variations in the estimates of the stocks

of materials on hand and in operation, both of which affect the consumption and production figures, it must be obvious that a period of no stock on hand would be extremely desirable. The equivalent of this can be obtained by splitting shipments into various bins so that one bin will be entirely cleaned out and another bin containing a definite quantity of material would be all the stock on hand at that time. This procedure is perfectly possible in all plants and should be undertaken at least every fortnight. In this way, constant checks on the stock of raw materials can be made. Scores of companies however, have only one bin or pile to which they add and from which they take at the same time. This continues for years oftentimes and the overages and shortages amount to absurdly high quantities.

The Personal Element in Plant Yield

The Executive Demand for Consistent Yield As a Cause of Inaccurate Yield

When an executive looks over a set of yield figures, he usually compares them with those of the previous month and inquires about those that show marked changes. "What are the reasons?" he asks. This request is transmitted through the usual channels until it finally reaches the operating man in charge of the unit. Usually he is unable to explain the inconsistency and is considerably embarrassed by the searchlight of investigation. Therefore, next time he takes some pains to avoid a repetition of the inquiry. In other words, he usually adjusts his yield so that it will be consistent with the last month's yield. This can be done very easily by subtracting from or adding to the stocks in operation. Then next month or next fortnight, whenever the next calculation is made, he balances up his stock so that over a period of months there will be no great shortage or average so far as his measurements are concerned and his yields will be reasonably consistent. Therefore, executive attention ceases to be focused on that unit.

Too Much Emphasis on High Yields Unwise

Still another phase of the same problem is the desire on the part of operating men to obtain high yields. Praise is usually lavished on high production and yield. There is a great tendency toward dishonest boosting of yields, due to this fact. A great many executives flatter themselves that dishonesty does not exist in their plant and a large majority of them are being awfully well fooled on that point. They will point with pride to the one or two men who are discharged for dishonest practices—they are the men who are caught. Many ingenious methods have been devised to beat the game. Sometimes they will cheat another unit from which a raw material is obtained without its knowing it. Sometimes it is possible to consume more material than is recorded and to run ultimately into a shortage which, in the average plant audit, cannot be pinned on to them, due to a number of possible flaws in the system, such as inaccurate weight delivered to the plant, unreliable inventory measurements, etc. The operating men cannot be blamed too much for this situation. It is a product of their environment and of the system. If executives would remove the tendency toward dishonesty, there would be no dishonesty. This can be done by setting a premium on accuracy of yield rather than on efficiency and high yields.

Executive Sense of Balance Necessary

The effect of dishonesty on plant yield figures is as disastrous. It makes them useless. The first job of a plant executive should be to understand the operating methods so thoroughly that he is certain of the accounting system and knows accurately the possible variables. It is somewhat amusing but more pathetic to see a solemn conference as to why such and such a unit dropped 2 points in yield and to realize that the yield cannot be calculated more accurately than plus or minus 5 points. The trouble is not with an individual executive so much as with the system. The plant executive is asked those questions by his superior who is more and more out of touch with plant methods and he must give the answer which the plant operator gives to him. He can object to the question and point out the fact that it is foolish to worry about so small a variation when you don't know the figure as accurately as that, but generally he does not know this and would not dare say so if he did know it. So in turn, he demands of his subordinate the same unintelligent analysis and therefore, we have a continuation of these absurd conferences, all of them trying to "pass the buck" on a question that had no right to be asked in the first place.

The problem of accurate yield is then twofold. First, a system must be installed upon which reliance can be placed, and second, a personnel must be developed which is in sympathy with the system and which understands it thoroughly. There is not space here to discuss the problem adequately. We have developed some of the underlying principles and pointed out some obvious weaknesses in existing systems. It is vital to emphasize the necessity of intelligent work on this problem. It lies at the root of accurate costs and the whole morale of the organization may be undermined because the system under which it works is lax and permits and even encourages dishonesty.

Use of Rubber in Road Making

Experiments are being carried out by the Colombo municipality in the use of rubber as a road-surface dressing, according to *Commerce Reports* for July 3. The dressing, which is the invention of a Ceylon rubber planter, is now being used on a portion of Darley Road, which is one of the most used thoroughfares in Colombo, Ceylon. This solution was first tried on a road of the Deviturai rubber estate, where it has been in use for the past 13 months. A short stretch was later laid in the municipality of Galle. The present test, however, is the hardest to which the new solution has been put.

The solution is made from pure bark and scrap rubber. The method of laying is similar to that employed with tar and asphalt preparations, it being heated until liquid and then spread on the road with brooms. Fine gravel is then sprinkled over the solution and a steam roller binds the two.

The experiments so far show that this solution is easier to handle than tar. It is a secret formula and the inventor is still working toward its perfection. He hopes to evolve a solution which may not only be used as a binder, but also may be spread to a depth of 1 or 1½ inches so as to be a road surface in itself.

The cost of the liquid-rubber road dressing is 50 to 75 per cent more than that of tar, but it is expected to last two or three times as long.

The Native Sugar Industry of Szechuen Province, Western China

By H. K. Richardson

THE sugar district of Szechuen province, China, is a rather sharply defined area of about three thousand square miles. The most important section of the district parallels the main road from Chengtu to Chungking for a distance of 100 miles between the cities of Chien Chou and Nei Chiang. Fig. 1 shows a sketch map of the territory. The Lu Ho River runs the whole length of this section and serves as a cheap distribution system whereby the sugar products reach about half the population of the province, or 30,000,000 people.

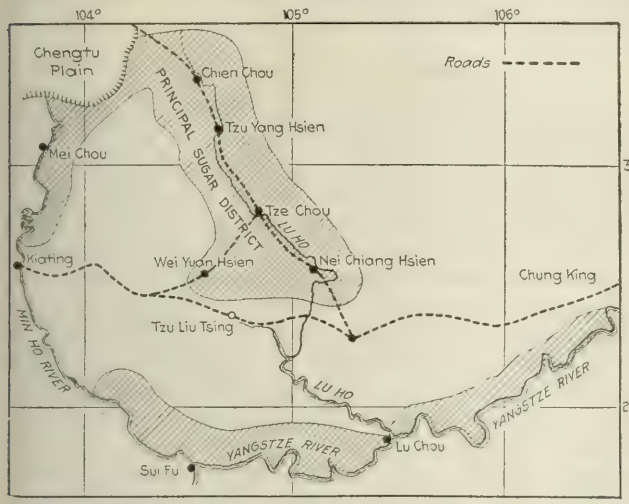

FIG. 1—SUGAR DISTRICT. SZECHUEN PROVINCE, CHINA
Shaded portions represent principal producing sections.

On one trip through this section the writer has seen ten crushing and evaporating houses within a radius of a mile. About half of all the land was given over to the growth of sugar cane. This preponderance of sugar interest holds all over the section.

In *Commerce Reports* for 1915, Consul-General Baker estimated that this section produced about 240,000,000 lb. of sugar per year. From personal observation and Chinese sources the writer feels that about 150,000,000 lb. would be a better figure. Even this is about half the Louisiana crop of 1920-21.

There are two other nearby sections where the growing of cane is a sizable industry. One of these is the river banks of the Yangstze from Sui Fu to Chungking. Hosie in his "Report on Ssuch'uen" speaks of this as a large sugar country. Although the author has seen this cane growing, he has never been in a position to judge of its extent inland. The other section is the banks of the Fu Ho between Kiating and Mei Chou, where the writer has seen wonderful stands of cane ripening in October. Small patches of cane are grown all over the province in favored spots, but these contribute very little to the sugar industry, being used locally for chewing.

Growing of the Cane

There are three kinds of sugar cane grown in Szechuen: *Hong Gan* or red cane, *Lo Han* or large white cane and *Lu Ma Gan*, a small white cane.

The red cane, or *Saccharum officinarum var. rubricaule*, grows to a height of 8 ft., with a heavy stalk 1¼ to 1½ in. in diameter. The joints are 8 to 12 in. long. The stalk alone is 5 ft. long and weighs about 4 lb. This cane is used exclusively for chewing purposes. A single stalk sells for 80 to 90 cash (3 cents) and is cut up by the retailer and sold in small pieces at a few cash each. This takes the place of chewing gum for the Chinese.

FIG. 2—RED SUGAR CANE MARKET

The red variety is grown in quantity outside the regular district. Tze Chang, Pa Chow, Kai Hsien and Ho Chow are famous markets for this variety. The cane is a quick grower. It is planted in February and is ready for use in August, although left standing until frost in December. A supply is stored in pits under cover of the leaves and is used till the new crop arrives. It is said that the red color or the sweetness does not develop until the leaves are stripped from the stalk. A red cane market is shown in Fig. 2.

Wilson, in "A Naturalist in West China," calls all the white cane *Sacchrum officinarum var. sinense*, but the Chinese distinguish two canes as indicated above. The two canes vary only in size, the large being about 1½ in. in diameter, while the smaller is slightly under an inch in diameter. The canes grow 10 to 15 ft. high and are 7 ft. when topped, with twelve to fourteen joints. A load of twenty stalks of the large variety will weigh 80 lb. They sell at the market for 10 cash a catty (1.33 lb.) or about ¼ cent per lb.

These canes are planted in February and harvested in December or January or before frost. The tops alone are used for the planting. They are laid flat in trenches 18 to 24 in. apart. Four to ten sprouts come up from each joint, only three or four of which are permitted to mature. A small stand of this cane is shown in Fig. 3.

FIG. 3—STAND OF SUGAR CANE IN NOVEMBER, NEAR TZECHOW SZE

The land is planted to cane on alternate years only. Wheat, peas and beans are the crops in the intervals. In a few cases the small white cane is used as a perennial, two or three crops being taken from one root.

Raw Sugar Production

Crushing

The crushing of the cane and the evaporating of the juice is always done near the cane fields and away from the cities. The ripened cane is cut by hand and carried to the crushing mills by coolies. The cane is crushed between vertical stone rollers, driven by cows or buffalos. Two limestone rollers are provided with holes around their upper sections, into which oak wedges are driven. These wedges or cogs engage as gears so that the two rolls revolve together but in opposite directions. The rollers have wooden shafts in each end. The lower shafts are provided with iron inserts and rest upon iron ball bearings. The upper shafts project through a large beam supported on stone pillars. The drive roll shaft extends 4 ft. above the beam. To this is tied a bent arm carrying the harness for five draft animals. The driven roll is held against the drive roll by means of a filler block and wedge set in the beam against the upper shaft of the driven roll. The cane is fed through a hollow cast-iron guide shaped to the rolls. About 10,000 catties (13,333 lb.) of cane is crushed per day, two passages through the crusher being the usual practice. Fig. 4 is a photo and Fig. 5 a cross-section of such a mill in the Chien Chou section.

Evaporating

The juice from the rolls runs by gravity to a receiving tank in the evaporator house near the crushing mill. Here a series of iron pans 2 ft. in diameter are set into brick and Chinese cement over a grate and flue. The weak juice is placed into one of the three pans over the grate and dipped up into the pans along the flue as it thickens, thus following direct-current rather than counter-current practice. The last pan in the series is placed to one side of the flue and is called the cold pan. When the juice has reached the right thickness, it is thrown into this cold pan and beaten with an iron paddle until it crystallizes. It is then poured while hot into bamboo basket containers, holding about 40 lb. and permitted to cool. The material resembles maple sugar and is called *Huang t'ang* or yellow sugar by the natives. These baskets are shipped to market in this condition. Where boat carriage is to be used, the sugar is poured into wooden tubs about 3 ft. in diameter. Each batch of sugar makes a layer 2 to 3 in. thick. The different batches are separated by sheets of paper. Fig. 6 shows a set of pans used in a refinery to recover sugar from the sirup made up from dirty sweepings. The arrangement of the pans is shown in Fig. 7.

Nothing but scum is removed in the evaporating process. The imperfectly crystallized raw sugar is an important item of the internal trade of the province. A very large proportion goes into candy. The street vender with his little stove and iron plate is seen all over the province. He breaks up the plinths of *Huang t'ang* and melts them in the hot bowl. The molten sugar is dropped over bamboo sticks on the iron plate forming the Chinese youngster's lolly-pop—it is as popular in China as in this country and consumes a large part of the sugar supply.

Refining the Raw Sugar

A considerable amount of the *Huang t'ang* is submitted to a refining process that gives a whiter sugar called *Beh t'ang* or white sugar. This industry is entirely separate from the process described and is nearly always carried on within the walls or just outside the walls of the large cities. Tze Chou and Nei Chiang are the cities in which most of the refining is carried on.

The raw sugar to be refined is placed in large earthen jars with bamboo sieve bottoms. A layer of clay mud about an inch thick is spread over the sugar and the jar set over a water jar. For about a month the jars are exposed to the air night and day. The moisture absorbed by the clay trickles down through the mass of sugar and leaches out the molasses, leaving a light brown granular sugar. The climate is very humid during the months that the refining is going on, so a considerable amount of water is absorbed. The light brown sugar is stored in bins until the spring months. It is then spread out on bamboo mats to dry and bleach in the sun. This sugar sells at twice the price of the raw material. Unless carefully handled, some of the mud from the top layer gets into the sugar and causes complaint. If too badly contaminated this dirty sugar is dissolved with all the sweepings and evaporated down at the refinery. Fig. 8 is a photo and Fig. 9 a cross-section of the refining jars.

The Chinese in the Tze Chou territory claim that 48 oz. of cane yields 8 oz. of the white sugar, *Beh t'ang*. This 16 per cent extraction yield looks almost too good considering the crude processes used, although the writer did not have means of checking this figure.

The molasses that collects in the lower jar of the set is called *Lou Tzu T'ang*. It is a black liquid and

FIG. 4—STONE CRUSHING ROLLS HOUSED UNDER CONICAL THATCHED ROOF AT CHIENCHOU WORKS

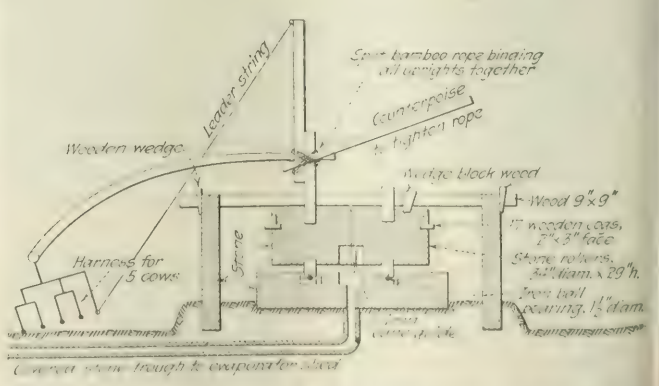

FIG. 5—CROSS-SECTION OF STONE CRUSHING ROLLS AT CHIENCHOU

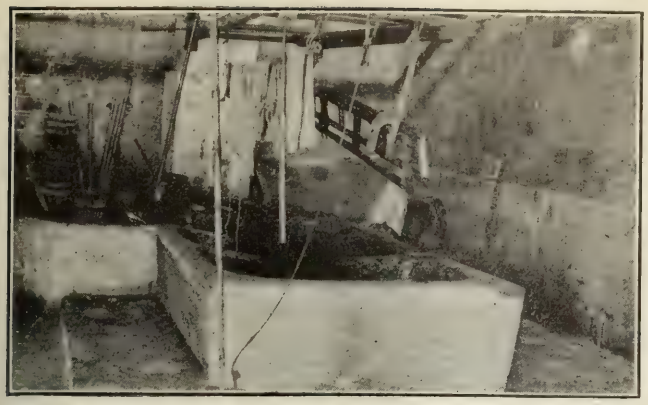

FIG. 6—EVAPORATING PANS IN REFINERY AT TZECHOW SZE, SHOWING TOOLS STORED IN PANS DURING SLACK PERIOD

is carried into nearby villages, where it is used as a sirup for rice cakes, diluted with water and used as a beverage in the fields or boiled up with popped rice—a variety of rice corresponding to our popcorn. This latter material is cut into slabs like our peanut bars and is a very popular confection.

Uses of the White Sugar

White sugar is dissolved up in a minimum of water, placed in jars and the liquid permitted to evaporate naturally. The large crystals formed are called *Bin T'ang* and correspond to our rock candy. Those who wish the best sugar, free from grit, grind this sugar up in a mortar. It is also sold as a sweetmeat.

At the time of the festivals white sugar is melted up at street stalls and cast into molds. In this way hollow idols and animals are made, corresponding to our familiar hollow chocolate Easter bunnies.

In the sugar districts a large amount of the white sugar produced is consumed locally to preserve fruits and make the glacé ginger root so much in demand in this country. The dry preserved ginger root and wet comquots are familiar to all who have eaten in Chinese restaurants in this country, but there is scarcely a fruit or vegetable that is not sugar preserved in the Tze Chow district. Preserved peppers, apples and carrots are among the specialties of this section. A few years ago Tze Chow had eighteen shops that did a yearly business of about $150,000 and consumed about a tenth of the sugar refined in the town.

Barley Sugar and Rice Sugar

The favorite candy of the Chinese adult is a white chewing candy called *Ma T'ang*. This very popular confection is made from a rice sugar which, on account of the method of its manufacture, is sometimes called barley sugar.

The manufacture of this sugar is essentially a home and small-shop industry. It is prepared by steeping 130 catties of dry rice in hot water and mixing the mash with 9 catties of barley sprouts which are produced by the germination of dry barley for 6 to 8 days in warm water. The mash is mixed in a covered tub with a sieve bottom which is placed over a pot of boiling water and steamed for 18 hours. The extracted material trickles down into the pot and is concentrated as the water evaporates. At the end of 18 hours the concentrated sirup weighs 80 to 100 catties. This sirup is boiled down and pulled to form a white candy.

The process is usually carried on "from supper to breakfast" according to the Chinese. This is from 3 p.m. to 9 a.m. During the night only a little attention is needed to keep the fire going. The yield is usually 3 lb. of heavy sirup to 4 lb. of rice. The material is very similar to the Japanese *Me Zu Amee* and is a delightful candy of much milder sweetness than cane sugar candy. On account of the nature of the industry no figures as to its extent can be given.

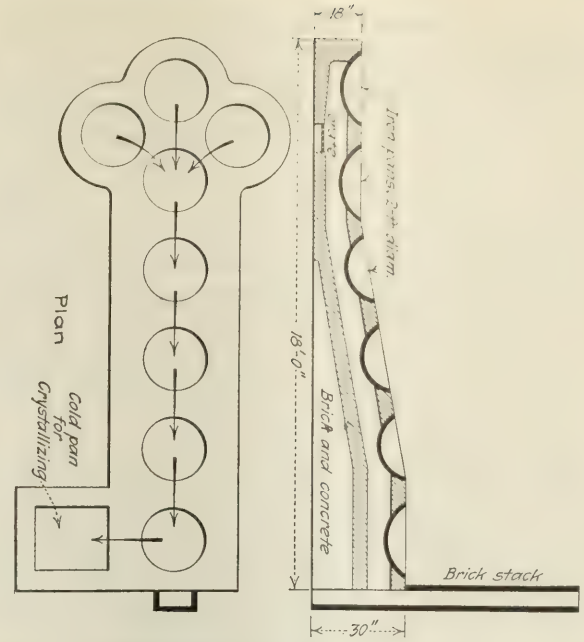

FIG. 7—CROSS-SECTION AND PLAN OF RAW JUICE EVAPORATOR AT CHIEN CHOU

FIG. 8—COMPLETE SUGAR REFINERY

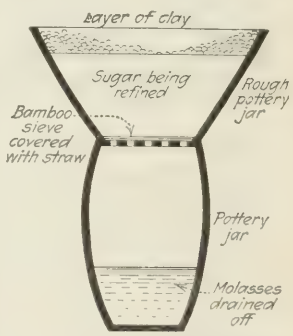

FIG. 9—CROSS-SECTION OF REFINING JARS

Economics of the Industry

The raw cane sugar sells in the district at a little over 3 cents per pound. On the estimated production of 150,000,000 lb. per year, this means a business of $5,000,000.

It is difficult to tell how much sugar is refined. On one of our trips to Tze Chow a Chinese business man said there were twenty-seven refineries in the Hsien (township) that did a business of from 20,000 to 50,000 taels per year. For them all this would mean about $1,000,000 a year business, which at 6 to 7 cents

per pound represents a total of 15,000,000 lb. of sugar refined in this one town. Probably the total refined in the province would be double this amount.

The net extent of the industry can be seen from the table below:

Value of 150,000,000 lb. of raw sugar	(gold)	$5,000,000
Value of 30,000,000 lb. of white sugar		2,000,000
Total		$7,000,000
Value of raw sugar in refined sugar		1,000,000
Net value of the industry		$6,000,000

This may not appear to be a very large industry to an American, but to the Chinese with a 10 cent per day wage, the prevailing rate in west China, it means a considerable industry. Stated in cash, the common coin in circulation among the workmen, the business done per year is 18,000,000,000 cash.

Sugar is the dominant idea in the minds of the 3,000,000 persons that inhabit the district. Nei Chiang and Tze Chow are primarily sugar towns. The carriage of the sugar to distant points requires the employment of a large number of men, for there are no railroads or pack roads in the district, so coolie carriage and boats drawn by trackers must be used.

Modernization of the Industry

Suggestions for the erection of a refining plant of 30 tons of pure white sugar per day for the year received favorable attention from the Chinese. The unsettled conditions brought about by the war have stopped all further plans on the subject. A modern plant of this size on a co-operative basis should be a good investment, for the Chinese like the foreign white sugar and would be willing to pay a premium for it. Loaf sugar sells in the Chinese stores by the piece as a sweetmeat at present.

On the other hand, a modern crushing and grinding plant would probably not be justified at present. The interest on the investment and the high cost of steam power could not compete with the abundant and cheap labor supply. However, technical conditions in the province and especially the district under review are ideal for a very large sugar industry. It will only be a question of time when the Chinese realize that a modern sugar industry in this section would obviate the necessity for their large present importation of sugar from foreign sources.

The Fertilizer Industry and Market in South Africa

In *Commerce Reports* for June 12, 1922, Trade Commissioner Perry J. Stevenson of Johannesburg makes a very interesting résumé of the fertilizer situation in South Africa. The occasion for this is the completion of a very large plant with a capacity of about 100,000 tons of fertilizer per year by the DeBeers Company, the diamond producer. It has been estimated that the present consumption of fertilizer in South Africa is somewhat below the capacity of this plant, but this is due to the fact that South African farmers have not learned the lesson of intensive cultivation and consequently the yield per acre is much lower than in other parts of the world. Furthermore, the soil is becoming more and more impoverished each year.

In South Africa considerable fertilizer is imported from outside. In 1913 63,000 tons was brought in, but this fell during the war to as low as 16,000 in 1918. Some recuperation has been made so that in 1921 nearly 30,000 tons was imported. A large percentage of this was superphosphate, with miscellaneous manure fertilizers, basic slag and bone fertilizer making up the remainder. Great Britain, the Netherlands and Belgium in 1920 were the principal exporters to South Africa.

For the first time since the war German producers have reappeared in South Africa and the German Potash Syndicate has resumed operations through an agency in Cape Town. Superphosphates are being imported and several large shipments have been made. At the present time it is too early to estimate whether local producers can meet German and other competition, but a tariff may be invoked.

Accelerated Weathering of Paints on Wood and Metal Surfaces*

By Harley A. Nelson
Research Laboratory, New Jersey Zinc Co.

The weathering of exposed surfaces involves variations of a cycle which includes light, temperature changes and moisture. Apparatus in which to artificially reproduce and observe the effects of these singly and combined has been constructed. Special 30-in. quartz mercury arcs furnish the source for ultra-violet (actinic) rays. The rate at which these deteriorate has been estimated with the means at hand. The useful rays appear to be in the region $\lambda = 3000$ Angstrom Units, or near the end of the sun's spectrum. Temperatures equal to summer heat on exposed surfaces—60 deg. C. (140 deg. F.)—are provided by the light. During the winter months advantage has been taken of low outdoor temperatures. Moisture, simulating heavy rainfall, is provided by a revolving spray. The pressure is maintained as high as practicable to promote erosion of decomposition products from the surface. An atomizer provides means for maintaining a saturated atmosphere.

Exposures are made at 28 in. from the light source. The panels are of selected white pine, or standard grade iron, 6 by 12 in., painted according to approved practice. For warm seasons, the cycle most used has been: light 24 hours (temperature 50 to 60 deg. C.), cooling, followed by moisture 24 hours (temperature 5 to 10 deg. C.). During cold weather 24-hour outdoor exposures have been added. Exposures have usually extended for periods of 60 to 90 days, with daily inspections.

Loss of gloss and formation of removable "chalk" follow in the order that these develop under normal outdoor exposure. Saturation of the film accelerates chalking under the ultra-violet light. Freezing saturated films promotes the formation of removable chalk. "Checking," developing gradually into deep cracking and fine scaling, has not been reproduced. Cracking has been reproduced to a limited extent by periodic exposures to low temperatures. Lack of adherence is evidenced by blistering and peeling when the saturated panels are exposed to the heat of the quartz mercury arc (50 to 60 deg. C.).

The relative susceptibilities of paints containing lithopone to light darkening are readily determined. The relative tendencies of tinted or colored paints to fade and discolor under light and moisture, are revealed by exposure.

The test has been applied to paints applied on metal surfaces with encouraging results.

The Technology of the Carbon Electrode Industry—I* The History of Its Development

Beginning With Sir Humphry Davy's Experiments in 1800 with the Electric Arc, the Author Presents a Technical Description of the Evolution of the Electrode Industry and Briefly Reviews the Present-Day Applications of the Carbon Electrode in the Chemical and Metallurgical Industries

By CHARLES L. MANTELL
Division of Industrial Chemical Engineering, Pratt Institute, Brooklyn

IN WRITING the biography of a living man one of the first things to be mentioned is his age, for that gives an idea of the times in which he has lived and the experiences he has passed through. This, in a general way, is also true of an industry, for its age at least hints at the state of perfection to which it has been brought. To say that the manufacture of carbon electrodes on a commercial scale is but half a century old is therefore equivalent to calling attention to its phenomenal development.

It shall be the purpose of the present article to review briefly the technical history of this development, but before attempting this review it is perhaps desirable to direct attention to a condition which is peculiar to the carbon industries. While most industries have a more or less abundant literature, with numerous books, pamphlets and articles, the manufacture of carbon electrodes is a notable exception. Were it not to be considered sarcasm, the industry might even be referred to as a "black art," first because of the secrecy usually surrounding its processes, and second, because of the absolute physical dirtiness of the usual electrode plant. Carbon works have generally been regarded as fortications, through whose gates only the initiated might enter. Most of the manufacturers have been of the opinion that the less said on the subject the better for them. One reason for this, perhaps, is that in Europe the art of manufacturing high-grade electrodes was always regarded as a secret, of which only a few had definite knowledge.

Early Experiments Lacking Commercial Significance

Sir Humphry Davy, in 1800, was probably the first to employ carbon electrodes in connection with the electric arc. His electrodes were made of charcoal, and were simply points or rods cut out of carbonized wood. As a result, they were neither dense nor homogeneous. It can easily be seen that such carbons were rapidly consumed, not especially surprising when we consider the current and voltage he used. He employed the great battery of the Royal Institution, constructed after Wollaston's design, consisting of 2,000 pairs of plates, from which he obtained an arc of approximately 4 in. in length. It is highly probable that if we were to take some of our modern electrodes and subject them to such an arc, they, too, would be quickly consumed, for oxidation of carbon at the temperature reached in the arc is very rapid.

Foucault was one of the first to make use of "deposited carbon," or the coke that condenses on the insides of gas retorts. As early as 1846, however, Staite and Edwards patented a process of making carbon electrodes from pulverized coke and sugar, the mixture first being molded under a high pressure, and later the shaped mass was baked at a white heat. The electrodes were then dipped in a concentrated sugar solution, the assumption being that the sugar would enter the pores and make the mass denser after a second baking. About the same time Leonolt prepared carbons consisting of two parts of retort coke, two parts of wood charcoal and one part of liquid tar. The materials were worked into a paste, well kneaded, molded, pressed, covered with sugar or sirup, and subjected to a high temperature for 30 hours or more. Leonolt also tried, but with indifferent success, to purify carbons by immersing them in different acids before baking.

In 1850 Watson and Slater experimented on a similar basis and 7 years later Lacassagne and Theirs attempted to purify electrodes by immersing them in fused caustic soda or potash, in the hope that they might thus change the silica in the carbons to soluble silicates. After fusing, the electrodes were steeped in hot water and exposed in a porcelain tube to a current of chlorine gas. It was supposed that the various earths not affected by the soda or potash would be converted into volatile or soluble chlorides, thus yielding a purer carbon.

Not long after these experiments, which were of no practical value, Curmer conceived the idea of making carbons of a mixture of lampblack, benzine and turpentine. This mass, after being kneaded, pressed and baked, left a porous coke, since the benzine and turpentine volatilized in a large measure during the baking process. Curmer attempted to increase the density of these electrodes by saturating them with resins and subjecting them to a second baking.

Jacquelain, formerly a chemist at the Ecole Central at Paris, made carbons by using the hydrocarbons obtained in the distillation of coals, turf, etc., and also from the products resulting from the carbonization of these materials in sealed vessels. He obtained fair results, but never worked out a practical method or attempted to engage in the industry commercially.

Gaudin worked on electrodes which he made of lampblack. At that time, however, the price of lampblack was so high that he was obliged to seek some other material. He heated resins, pitch, tars and oils in

*Editor's Note—This is the first of a series of six articles dealing with the technology of the carbon electrode industry. The subsequent articles will discuss raw materials; calcining and calciners; grinding, mixing, molding and extrusion; electric and gas-fired baking and furnaces; and cleaning, machining, testing and shipping.

closed vessels, and obtained sufficiently pure carbon upon their decomposition. The volatile products of these substances were condensed and collected to be used again in mixing. He proceeded by pulverizing the carbon left after the decomposition and mixed it with a certain percentage of lampblack, using the condensed volatile products as binding material. This mixture was well kneaded, and molded with steel molds under the pressure of a powerful hydraulic press. The electrodes, after being baked, were considered to be superior to those in commercial use at the time.

The Beginnings of the Industry

From a commercial point of view, Carré appears to be the first to have had conspicuous success in producing carbons. He may justly be considered the founder of the industry.

The undeveloped state of electric lighting at the time had a great influence upon the work of these early investigators. It will be observed, however, that they were not far out of the way and that present-day practice differs from theirs only in that manufacture is assisted by more perfect mechanical methods.

When Carré studied the problem, the Gramme machine had just appeared and a host of inventors were struggling to construct a good arc lamp. There were demands for a good carbon that was practical in every respect, so that on the whole the time was very favorable to the founder of the arc-lamp carbon industry. It is interesting to read Carré's own account of this work:[1]

> The superiority of artificial carbons for various experiments and the possibility of purifying, with alkalis, acids, aqua regia, etc., the carbonaceous powders that enter into their composition led me to seek some means of producing them economically. By moistening the powders, either with sirups or gums, gelatine, etc., or with fixed oils thickened with resins, I succeeded in forming pastes sufficiently plastic and consistent to be forced into cylindrical rods through a drawplate placed at the bottom of a powerful compression apparatus of about 100 atmospheres. Carbons are now manufactured by this process and I have at various times presented some of them to the Société d'encouragement.[2]
>
> These carbons have three or four times the tenacity and are much more rigid than retort coke; cylinders of 10 mm. diameter and 50 cm. in length may be used without any danger of splintering during a break in the circuit. They may be as easily obtained in the slenderest diameters (2 mm.) as well as in the largest. Their chemical and physical homogeneity gives great steadiness to the arc, their cylindrical form, combined with the uniformity of their composition and structure, causes their cones to continue as perfectly shaped as if they had been turned in a lathe, and therefore there are no occultations of the point of maximum light like those produced by the projecting and comparatively cold corners of retort carbons. They are not liable to the inconvenience of flying into splinters when first lighted, as the others are, in consequence of the great and sudden expansion of the gas contained in their intercellular spaces which sometimes exceed 1 c.c. in capacity.

Carré's carbon mixture, which was patented Jan. 15, 1876, was as follows:

Very pure coke, finely pulverized	15 parts
Calcined lampblack	5 parts
Sirup of sugar	7 to 8 parts

The whole mixture was well pounded together, kneaded and worked into a hard paste. It was afterward pressed through a drawplate by a hydraulic press and the carbons or rods piled into retorts, where they were baked at a high temperature.

The general operations in the manufacture of electrodes have remained practically the same for the last century. Thus Carré has described the crude beginnings of the industrial operations of calcining, grinding, mixing, shaping (either molding or extrusion) and baking. Improvements have been in every one of these, from the original crude coal-fired furnace with its low thermal efficiency and high fuel consumption, to the present highly efficient type of gas-fired continuous variety of multisection ring furnaces. It is a long step from the original calcining ovens, producing poorly shrunk coke to the gas-fired continuous vertical retorts used in the modern electrode plant.

In 1890 O. G. Pritchard[3], an Englishman, published a series of articles upon the manufacture of carbon electrodes. His raw materials and equipment are interesting to look back to, if for no other reason than that today, only 30 years or so later, they would not by any possibility be considered commercially feasible.

His raw material was foliated Ceylon graphite, which he purified by pulverizing to a fine powder and then treated with potassium chlorate and sulphuric acid. The sulphated and oxidized mass was further treated with sodium fluoride to get rid of silica as the volatile tetrafluoride. After calcination the material was ready for the use. Pritchard used purified cane sugar, caramelized, as a binder, explaining that he had failed in attempting to use tar oils, gums, hydrocarbons and beet sugar for the reason that all these substances produced undue porosity after the carbons were baked. He was unable to find a satisfactory measure for correcting this porosity.

Prichard's mixture was pressed through an orifice at the bottom of a vertical hydraulic press at a pressure of approximately 1,800 lb. per sq.in. The carbons were cut into the desired lengths by shears as the stream came out of the press. They were dried in an air-drying room and kilned in a very crude intermittent coal-fired furnace, much like those used at the present time for the small-scale manufacture of red brick.

Early American Developments

In the United States there was a patent granted in 1858 to De Grasses B. Fowler of New York for the process of making carbon plates by mixing ground coke with tar, shaping the mixture under pressure in molds, packing the shaped material in lime and heating it slowly in an airtight box to drive off the volatile matter. As the experimental arc light shown at Yale in 1871 used electrodes cut from retort carbon, it is not very probable that Fowler's patent was commercialized for other than battery plates.

David Thompson of Newark was probably the first American manufacturer. His first plant consisted of a small crusher, a mixing pan, a crude brick oven, some cast-iron molds and a hand-operated grinding and bolting outfit.[4]

Charles F. Brush and Washington H. Lawrence of Cleveland began to experiment on the manufacture of carbon electrodes about 1877. As they had found other materials unsuitable, they investigated the use of petro-

um coke, a source of supply of which they found ithin a mile or so from their workshop where the tandard Oil Co. had for years burned it under the oil ills in an effort to get rid of it. At first they used ie raw coke, pulverizing and molding it to shape in ectrodes about half an inch square and a foot long. s these electrodes had an abnormal shrinkage after aking, Brush invented the process of calcination of the oke prior to its fabrication into an electrode. Brush so invented a hydraulic press to impart greater ensity (due to greater pressure applied during shapng) than was obtainable with the hand press which as first used.

By the year 1878 Brush was manufacturing elecrodes on a commercial scale. It was electrodes such s these that Hall used in 1886 in his experiments hich led to the commercial production of metallic luminum.

The Discovery of Artificial Graphite

The next important event was the discovery of the ommercial manufacture of graphite. In 1893 in a lecure before the Société International des Electriciens, irard and Street[5] of the Société "Le Carbone" deribed a furnace for the conversion of carbon into raphite. The method consisted in causing a series of rcs to play over the surface of the carbon to be conerted. It was stated that an 85 per cent conversion as obtained. It is not known whether this method as ever commercialized.

In 1896 H. Y. Castner[6] patented a process for heating carbon electrodes by means of electricity so that a graphite-like form of carbon was produced." It ight be assumed that this anticipated Acheson's raphite electrode, were it not for the fact that Castner emarks that the resulting electrode "will be found o be of decreased density." The Acheson electrode, fter conversion to graphite, has a higher density than s amorphous raw material. Castner also states "that ie temperature produced is such that the carbon will ive off the more flammable material it contains." ccordingly his patent merely covered the electrical aking of carbon electrodes.

In 1896 E. G. Acheson, then of the Carborundum o., was granted a patent for the manufacture of raphite in an electric furnace. He heated carbon "in ssociation with one or more oxides to a temperature fficiently high to cause a chemical reaction between ie constituents and then continued heating until the ombined carbon separated out in the free state." He oes on in his patent to say: "It is not, however, mited to the use of oxides, as pure metals, their sulhides and other salts may be used; but for various easons the oxides are to be preferred."

Three years after the patent was obtained the Acheon Graphite Co. was incorporated and started buildng a plant at Niagara Falls, which is now the center f the industry. The company proposed that several istinct forms of the product were to be produced. One consists of forms or articles made out of amorhous carbon, with the desired amount of impurity dded, which will afterward be heated in an electric urnace and converted more or less to graphite." Acheson had been doing this work for a year or more revious in the furnaces of the Carborundum Co. He had made about "200,000 carbon electrodes, measuring 15 in. in length, with about 1-in. cross-sectional area, for use in the Castner alkali process, nearly half of them having been shipped to Europe."[7]

To quote again from Acheson, writing in 1899: "It is not the present intention of the company to enter into the manufacture of their product into the finished form for the general market, but rather to encourage those now engaged in making the natural graphite into articles of commerce to become buyers of their material, substituting it for the natural product now used." He states that according to the company's plans, "they will erect machinery for reducing coke to grains of the desired size, an electric furnace through which the prepared grains will pass in a continuous stream, a pulverizer for reducing the grains as they are received from the furnace, and a scalping sieve through which the product from the pulverizer will pass, so that the particles exceeding 1/200 in. in diameter may be removed. The final flour will contain an amount of pure graphite proportional to the percentage in the original coke."

It is interesting that graphite was first shown to be an elementary body and an allotropic form of carbon in the first year of the nineteenth century and in the last year was made to order in great quantities and was rapidly becoming an article of commerce.

Electric Furnace Electrodes

Up to the end of the nineteenth century practically all of the work in the carbon industry had in view the development of a satisfactory electrode for arc lighting. It was only in 1897 that Heroult and Hardmuth in France and Plania and Siemens in Germany started work on the development of suitable carbon electrodes for electric furnace work. They used anthracite coal for the first time as a raw material. Heroult manufactured electrodes in Canada in 1908 and in the United States in 1911.

A great deal of the credit for the development of the modern electric furnace electrode in the United States belongs to the National Carbon Co., which began, in 1906, experimental work to develop a furnace electrode several hundred times larger than the largest arc light carbon of that date.

The last quarter century has seen a most remarkable expansion in carbon electrode manufacture. Jehl[8] in 1899 lamented the fact that the center of the industry was at that time at Charlottenburg and Nürnberg in Germany, while there were so many other locations in the world with much greater natural advantages. He says: "There is no reason why England should not make high-grade carbons, why the United States, with its immense petroleum wells and natural gas spring, should not supply the world with all grades of carbons. Russia and other petroleum countries also have an advantage in starting carbon factories and supplying their own market; in fact, the whole carbon business seems to fraternize with the coal-gas manufacturers and petroleum distillers."

In the United States, in most instances, the industry has been dependent for its existence upon a source of cheap electric power for baking the electrodes, while in Europe the gas-fired furnace has been most generally

[8] Francis Jehl, "The Manufacture of Electric Carbons for All Electrical Purposes," The Electrician Publishing Co., London, 1899.

used for baking purposes. In this connection, although not directly connected with electrode manufacture, the names of Mendheim of Munich for his invention of the gas ring and chamber furnace; Escherich, for his gas-ring furnace; and Meiser, for his modification of Mendheim's furnace, first applied to the baking of pottery and then adapted to the baking of electrodes, deserve prominent mention in the history of the electrode industry. The Meiser (more or less adapted to local conditions) modification of Mendheim's furnace is largely used in the United States. It has replaced electric baking to a large extent, even in localities where power is cheap.

Thus it may be seen that the development of the carbon electrode industry has been along four lines: (1) Electric arc lighting; as this industry expanded, carbon development attempted to keep pace with it. (2) Electrolytic manufacture—e.g., alkalis, chlorine, aluminum and magnesium. (3) Electrothermic work—e.g., calcium carbide, silicon carbide, graphite, etc. (4) Electric furnaces—e.g., electric steel; copper, brass and aluminum alloys, ferro-alloys; nitrogen fixation.

Recent Development

One of the most important and useful industrial developments of recent years has been the extension of the use of electric furnaces. This was greatly accelerated by war conditions, war demands and war prices. This growth carried along with it an expansion of the electrode industry due to research and operating investigations. In 1919 there was a shortage of electric furnace carbons. Overwhelming demands swamped the manufacturers, not because of the lack of raw materials. but rather the inadequate manufacturing facilities.

The latest progress has been along the lines of much stricter specifications as to purity, resistivity, hardness and increased density of electrodes. The earlier workers tried to obtain higher densities by saturating the baked articles with binders and baking a second time. In the present day the end is reached by starting with higher density raw materials and calcining them in a manner which will increase this factor. One of the greatest plant problems of today is the maintenance of absolute uniformity of output.

The growth of the manufacture of carbon electrodes in the last 20 years or so has been tremendous. In 1899 the total value of electric furnace carbon output was $10,974,[9] in 1921 the total value of furnace electrodes produced was well over $10,000,000.[10] Electrode production is now the most important branch of the carbon industry; the output of brushes, which formerly was of greater significance only reached the value of $4,000,000 in 1921.[10] The following comments from a recent report of the Tariff Commission summarize the present status of the industry:

> The bulk of the production comes from the aluminum industry, which makes electrodes for its own use; and two carbon manufacturers, making chiefly graphite and amorphous electrodes respectively. Another large company was organized during the war to make amorphous electrodes. There are also a number of smaller concerns producing electrodes.
>
> The bulk of the production is from the states of Pennsylvania and West Virginia and from the Niagara Falls district of New York. The largest plant is probably one in New York.
>
> The entire demand in the United States can be supplied by domestic sources. The production at present probably exceeds the consumption.[10]
>
> The chief foreign producers are Germany, England and France. Carbon products are made in most of the countries of Europe and in Japan.

The essential rôle of the carbon electrode in industry and in modern life has recently been pointed out by Hinckley,[11] who has shown carbon electrodes enter into the manufacture of the following materials:

Electric steel, ferro-alloys, calcium carbide, silicon carbide and related abrasives; aluminum, calcium and magnesium metals; phosphorus and phosphoric acid electrical resistance wire; titanium and zirconium; carbon disulphide; tungsten; fixed nitrogen (cyanamide) sodium; caustic soda and chlorine; and all of the electric furnace alloys. The electrode today is therefore an essential part of our modern existence.

The second of this series of articles will discuss the raw materials for carbon electrode manufacture. It will appear in a subsequent issue of this magazine.

Evaporation of a Liquid Into a Gas

By W. K. Lewis

Head of Department of Chemical Engineering, Massachusetts Institute of Technology, Cambridge, Mass.

A LARGE amount of work has been done on the evaporation of water into air at temperatures below the boiling point. The dynamic equilibrium corresponding to the evaporation of water into air counterbalanced by the flow of heat from the air into the water is the basis of wet-bulb thermometry, the most useful method of determining the humidity of air. In 1886 Desmond Fitzgerald pointed out that the rate of evaporation of water into air is a fraction of the difference in partial pressure between the moisture in equilibrium with the evaporating water and the actual moisture content of the air in contact with it. It is true that Fitzgerald did not assume the rate of evaporation linearly proportional to this difference, but added a small correction term proportional to the square of the difference. Barrows and Babb made a large number of determinations of evaporation from the surface of Maine lakes and while their experimental determinations were subject to a large percentage variation, none the less their results substantiate this proportionality. More recently Willis H. Carrier has shown that the rate of water evaporation is, within experimental error, proportional to partial-pressure difference. The following is an analysis of the mechanism of such evaporation.

Preliminary Assumptions

For purposes of formula derivation assume a long tunnel through which unsaturated air is flowing at constant mass velocity. The walls of this tunnel are non-conductors of heat. Along the bottom of the tunnel is placed a mat or wick permanently wet with water supplied from below as evaporation takes place above. The water is furnished to this wick at every point at a temperature exactly equal to that of the water on the upper surface of the wick at that point. There is no motion of the liquid water parallel to the axis of the tunnel. The mass velocity of the air over the water is constant and sufficiently low so that heat generated by friction may be neglected.

The unsaturated air entering this tunnel will become humidified in passing through it owing to the evapora-

---

[*] Abstracted from *Mechanical Engineering*, for July, 1922.

ion of water. In consequence, the temperature of the ir will fall, and if the tunnel be sufficiently long, the ater and air will ultimately come to equilibrium.

Notation

In the formula to be derived, the following notation s used:

A = Area of liquid in contact with gas.
H = Absolute humidity of gas, or parts by weight of vapor per part by weight of vapor free gas.
h = Surface coefficient of conductivity of heat between gas and liquid, or B.t.u. per unit time per unit surface area per unit temperature difference.
k' = Coefficient of diffusion, or parts by weight of vapor diffused per unit time per unit area per unit absolute humidity difference.
k = Coefficient of diffusion, or parts by weight of vapor diffused per unit time per unit area per unit vapor pressure difference.
p = Partial pressure of vapor.
P = Total pressure of vapor and vapor-free gas (i.e., barometer).
θ = Time.
t = Temperature.
r = Latent heat of vaporization.
s = Humid heat, or number of heat units necessary to change the temperature of unit weight of vapor-free gas, *plus the vapor it contains*, 1 degree.
W = Weight of liquid evaporated.

Interaction of Water with Air

Now consider for the moment the conditions at any iven point along the length of this tunnel. At this oint the temperature, absolute humidity and pressure f water vapor in the air will be represented by t, H nd p. Since the apparatus is continuous in its operaion these conditions will remain unchanged at this articular point, but will vary from point to point along ne tunnel. The corresponding quantities representing ne condition of the liquid water in contact with the air t this particular point are t_w, H_w and p_w.

The mechanism of interaction of the water with the ir is as follows: There exists over the water what equivalent to a stationary film of air, which insulates ne water from the main body of the air. Through this ir film heat is diffused from the air into the water and rough the same film there is diffusing, in the opposite irection, the water vapor formed by evaporation on ne surface of the liquid. This evaporation cools the rface of water and, since it is available from no her source, heat must be supplied solely by diffusion om the air. The heat of vaporization must therefore e quantitatively compensated by the heat flow through ne surface film and the rate of evaporation is limited the rate of diffusion of vapor through the same film.

From the foregoing one can immediately write the llowing equations:

$$-\frac{dW}{Ad\theta} = k'(p_w - p) \tag{1}$$

$$\frac{dQ}{Ad\theta} = h(t - t_w) \tag{2}$$

$$dQ = -r_w dW \tag{3}$$

hence

$$p_w - p = \frac{h}{k'r_w}(t - t_w) \tag{4}$$

This last equation is the one normally used for calculating the humidity of air from wet- and dry-bulb thermometer readings. In it, variation in r_w is neglected and the term $h/k'r_w$ is assumed constant. For p in millimeters of mercury and t in deg. C., it equals 0.5. The equation implicitly assumes that the cooling of the air is differential—i.e., so small in the neighborhood of the point in question that the actual changes in temperature and humidity of the air, t and p (or H), are negligible.

Since

$$p = P\frac{\frac{H}{18}}{\frac{H}{18}+\frac{1}{29}} \tag{5}$$

$$t - t_w = \frac{k'r_w}{h}P\left(\frac{\frac{H_w}{18}}{\frac{H_w}{18}+\frac{1}{29}} - \frac{\frac{H}{18}}{\frac{H}{18}+\frac{1}{29}}\right) \tag{6}$$

Where H is small, as is usually the case below 150 deg. F., $\frac{H_w}{18}$ and $\frac{H}{18}$ are negligible compared with $\frac{1}{29}$, and one may write, as a close approximation,

$$t - t_w = \frac{kr_w}{h}(H_w - H) \tag{7}$$

where

$$k = 29k'\frac{P}{18}$$

It is obvious that h and k depend on the thickness of the air film and are therefore functions of the velocity of the air. It is, however, equally obvious that if air velocity be increased sufficiently to double the one, the other will double also. The ratio of h/k therefore remains constant, independent of velocity. This explains why the reading of a wet-bulb thermometer is uninfluenced by the velocity of air passing it, provided the velocity is sufficient so that any heat lost by radiation is negligible in comparison with that picked up by conduction.

The Relation $h/k = s$

Now consider the change in humidity and temperature of the air as it moves along the tunnel. Starting at the same point previously considered, the air will drop in temperature by an amount dt and increase in humidity by an amount dH. The heat given up by cooling must correspond to the heat of vaporization of the water picked up—i.e.,

$$-sdt = r_w dH \tag{8}$$

whence, assuming constancy of s and r_w,

$$H = -\frac{s}{r_w}t + \text{const.} \tag{9}$$

Assuming the tunnel indefinitely long, the air will ultimately become saturated at some temperature t_e, and humidity H_e. Since these conditions present equilibrium between the air and the water, evaporation will cease, and t_e and H_e are therefore the constant, fixed end-points of the process. Inserting these limits,

$$H_e - H = \frac{s}{r_w}(t - t_e).$$

We have now derived two formulas connecting H and t, both applying to this same process of evaporation—i.e.,

$$H_e - H = \frac{s}{r_w}(t - t_e)$$

and

$$H_w - H = \frac{h}{kr_w}(t - t_w)$$

These two expressions must therefore be identical. By the method of undetermined coefficients this can be true only provided the corresponding coefficients are equal, i.e.,

$$\frac{s}{r_w} = \frac{h}{kr_w}, \text{ or } s = \frac{h}{k}$$

and $t_w = t_e$, a constant; and $H_w = H_e$, also constant.

So far the discussion has been limited to water and air. Obviously, however, the same relationships must apply to any liquid and any gas with which its vapor is mixed.

The first of these equations, $h/k = s$, states that the coefficient of heat transfer divided by the coefficient of vapor diffusion through the gas film is constant, and equal to the humid heat of the gas. By means of formula 4 the ratio h/k can be calculated from the observed wet- and dry-bulb temperatures for any vapor-gas mixture of a known gas humidity. The experimental determinations of wet-bulb temperatures for water-air, water-carbon dioxide, toluene-air and chlorbenzene-air, and calculations for h/k given in Table I show that

TABLE I—VALUES OF h/k FOR VARIOUS VAPOR-GAS MIXTURES

	h/k Calculated From Experimental Results	Specific Heat of Gas
Water-air	0.236	0.238
Water-carbon dioxide	0.217	0.220
Toluene-air	0.238	0.238
Chlorbenzene-air	0.248	0.238

this ratio is in all cases substantially equal to the humid heat of the entering gas, which in this case was identical with the specific heat because the gas which was used was vapor free.

We have therefore demonstrated that, granting substantial constancy of s and r_w, and assuming H to be small, the ratio of the coefficient of diffusion of heat to that of any vapor through the gas film on the surface of the liquid is equal to the "humid" heat of the gas. Furthermore, during adiabatic evaporation of a liquid into a gas, the liquid being in dynamic equilibrium with the gas, the temperature of the liquid remains unchanged throughout the process and the end-point of the process is reached when the gas has cooled itself to saturation at a temperature identical with that of an ordinary wet-bulb thermometer.

Importance of the Relationship $h/k = s$

The importance of the relationship $h/k = s$ is very great. The term s, the humid heat, may be readily calculated for any case, regardless of whether the problem is primarily one of heat transfer or of diffusion. Hence if the heat-transfer coefficient h has been experimentally determined for a certain type of apparatus operating under definite conditions, the coefficient of diffusion equals h/s, and the capacity of this same apparatus may be predicted when functioning in diffusion processes—e.g., as a gas scrubber. Conversely, if k and s are known for definite conditions, h equals ks; in other words, one can predict the performance of a given apparatus for heat transfer from data upon the same equipment functioning as a scrubber.

These processes of diffusion of heat and of vapor are at the basis of the performance of all such equipment as humidifiers, dehumidifiers, water coolers, gas scrubbers, air driers, light oil stripping columns, and the like. The above relationships make it possible to study the performance of such equipment on a more rational basis than hitherto and to compare the effectiveness of different types of equipment even when the data on the individual types are obtained under widely varying conditions. The department of chemical engineering, Massachusetts Institute of Technology, expects to publish in the near future a series of articles showing various applications of these relations.

Liability for Death of Trespassing Children in Poisoned Pool

By a divided court the decisions of the lower courts have been reversed by the United States Supreme Court in the case of Van Britt and wife against the United Zinc & Chemical Co. (264 Fed., 785.)

The chemical company owned a tract of about 20 acres in the outskirts of the town of Iola, Kan. Formerly it had there a plant for the making of sulphuric acid and zinc spelter. In 1910 it tore the buildings down, but left a basement and cellar, in which in July 1916, water was accumulated, clear in appearance but in fact dangerously poisoned by sulphuric acid and zinc sulphate from the works of the company. The claimants had been traveling and encamped at some distance from the place. A traveled way passed about 100 ft from the accumulated pool. Two children of claimants on July 27, 1916, went bathing in the water, were poisoned and died. Claimants brought suit for the deaths and at the trial the judge instructed the jury that if the water looked clear but in fact was poisonous and thus the children were allured to it, the chemical company was liable. The U. S. Circuit Court of Appeals affirmed a verdict and judgment against the company.

In reversing this judgment the Supreme Court has said that an owner of land owes to trespassers no duty to remove even hidden dangers, though he cannot prepare a trap for trespassers whom he expects to come upon his land. And infants have no greater right to trespass upon other people's land than adults, and landowners owe them no duty to expect them and to prepare for their safety.

Further this court says a land owner owes no duty to children to protect them from hidden dangers on his land, unless he has directly or impliedly invited them to come thereon, so that he is not liable for the death of the children in an abandoned basement, filled with poisoned water, which could not be seen from the highway and thus attract them.

The court's decision rests upon the question whether the poisoned pool of water could be seen from the highway or any place where the children lawfully were and that it was what led them to enter the land. Since there was no evidence to show such attraction the court held the chemical company owed them no duty and therefore reversed the judgment. (42 S. C. Reporter, 299.)

Dissenting Opinion Holds to Humane Doctrine

Chief Justice Taft and Justice Day concurred in a dissenting opinion written by Justice Clark. They pointed out that from 1873 until this decision the Supreme Court of the United States had applied, in

such cases as this at bar, what is termed the "humane" doctrine and deplores this change to the "hard doctrine," or the "Draconian doctrine." The "humane" doctrine was established by a decision of the U. S. Supreme Court in 1873 (Railroad Co. vs. Stout, 21 L. Ed., 745) in a unanimous decision. Since then the Supreme Court of Illinois, on authority of the Stout case, held a city liable for the death of a child drowned in a similar pool of water not poisoned. Justice Clark says:

"Believing as I do that the doctrine of the Stout and McDonald cases, giving weight to and making allowance, as they do, for the instincts and habitual conduct of children of tender years, is a sound doctrine, calculated to make men more reasonably considerate of the safety of the children of their neighbors, than will the harsh rule which makes trespassers of little children which the court is now substituting for it, I cannot share in setting aside the verdict of the jury in this case, approved by the judgments of two courts, upon what is plainly a disputed question of fact and in thereby overruling two decisions which have been accepted as leading authorities for half a century, and I therefore dissent from the judgment and opinion of this court."

Sale of Parts for Unpatented Apparatus Used with Process Patent Not Infringement

The U. S. Circuit Court of Appeals has held that the sale of a single part for use in an unpatented apparatus for carrying out a patented process does not constitute contributory infringement of the process patent, in an action brought by the Electro Bleaching Gas Co. against William G. Miller and others. This holding has been upheld by the United States Supreme Court (42 Sup. Ct. 187).

The Electro company charged the defendants with contributing to the use and practice of the process of antisepticizing water, which rights it claimed under process patent No. 1,142,361, as granted to George Ornstein. The inventor originally applied for a patent on the apparatus as well as the process, but the request for the apparatus was rejected by the examiner of the Patent Office and withdrawn. The application upon which the letters patent were finally granted does not describe the apparatus in any of the claims but only the process of antisepticizing waters, although in the specifications the apparatus to be used is described and also illustrations of three kinds of apparatus which may be used are filed.

Apparatus Sold by Plaintiff for Use With Process

The apparatus by which the patented process is made operative, as shown by the figures accompanying the application, comprised an absorption tower, through which the minor flow of water passes downward to absorb an upwardly moving current of chlorine gas. The chlorine is supplied from a tank of compressed and liquefied chlorine gas from which a pipe leads into the lower part of the tower. The tank is provided with a shut-off valve and the supply pipe with a pressure reducing valve and a regulating valve. Water is supplied to the tower from any suitable source.

The infringement charged is a chlorine gas-pressure regulator, performing the same office and producing the same results as the pressure reducing and regulating valves of plaintiff's apparatus. The company had sold to the city of Chicago, for use in its municipal water plants, a number of complete sets of its apparatus. Later the city purchased from defendants a Miller chlorine gas-pressure regulator to replace the corresponding part in the company's apparatus. The city made this change, according to its assistant city engineer, because defendants' valves enabled the city to obtain a better regulation of gas flow from defendant's valves and a great saving in maintenance costs. The city of Kansas City made a similar change and the city chemist in charge of water purification said the reason was that plaintiff's valve mechanism was insufficient in capacity to get the required quantity of gas into the coke-filled tower.

The U. S. District Judge held that the sales of these valves constituted infringement of plaintiff's process patent, which judgment has been reversed.

It was not claimed that defendants had employed the process of the patent in suit, nor that they had made or sold apparatus for employing that process. Only they sold the pressure regulating valves to replace regulator valves furnished as a part of the apparatus sold by the plaintiff company. Defendant's valves were manufactured and sold by them for general use and were used in some flour mills.

The real question in issue was whether upon this state of facts a person selling a single part for use in an apparatus employed in manufacturing an article protected by a process patent is guilty of contributory infringement.

Distinction Between Process and Apparatus

The application for patent on the apparatus of Ornstein was denied by the Patent Office, and then abandoned by him. The Supreme Court has said: "A machine is a thing. A process is an act or a mode of acting. The one is visible to the eye—an object of perpetual observation. The other is a conception of the mind, seen only by its effects when being executed or performed." (Tilghman vs. Proctor, 102 U. S. 707). Again the Supreme Court, in Cochrane vs. Deener, 94 U. S. 780, said: "A process is a mode of treatment of certain materials to produce a given result. It is an act, or a series of acts, performed upon the subject-matter to be transformed and reduced to a different state or thing. . . . The machinery pointed out as suitable to perform the process may or may not be new or patentable; while the process may be altogether new, and produce an entirely new result. The process requires that certain things should be done with certain substances, and in a certain order; but the tools to be used in doing this may be of secondary consequence."

A process and an apparatus by which it is performed may be found in one patent, or they may be made the subject of different patents. And the court here points out that the valves sold by defendants in no wise affected the process, but at most the apparatus which was not protected by the patent.

A similar ruling was made by the Supreme Court in the case of Rumford Chemical Works vs. Hygienic Chemical Co., 30 Sup. Ct. 45. In another case it was of "the opinion that the line should be drawn to include those articles which are either parts of a patented combination or device or which are produced for the sole purpose of being so used and to exclude the staple articles of commerce." 207 U. S. 198.

Therefore the Court held that the defendants were not guilty of contributory infringement as alleged and the District Court was reversed.

Cast Iron as Produced in the Electric Furnace, and Some of Its Problems*

A Basic Electric Furnace Is Useful to Refine Cupola-Melted Iron, Reducing Sulphur and Gases to Any Extent Desired, and Producing Easily Machinable Castings, Very Tough and Strong, and With a Minimum of Defectives From Dirt or Blowholes

By George K. Elliott
Chief Metallurgist, The Lunkenheimer Co., Cincinnati, Ohio

THE first use of the electric furnace for gray cast iron in everyday production, and not in sporadic experimental heats, seems to have been in the iron foundry of the Lunkenheimer Co. at Cincinnati in the summer of 1917. Beginning with "cold charge" heats, the process soon underwent a logical change into the duplexing process, wherein the cupola was utilized for the otherwise costly melting period of the cycle. The first few months the furnace, a Heroult with basic hearth, was confined to melting cold charges of special low-phosphorus iron, desulphurizing, reducing the carbon by dilution with steel, adjusting silicon to suit the size and nature of the castings, and finally casting into parts for which semi-steel originally had been used.

Melting Cold Charges

This product perhaps came as near being the consummate semi-steel as is possible. This relatively expensive process soon developed into the tandem process and now is used only on rare occasions when small heats of special iron are desired. It is the writer's understanding that several foundries are using the cold-charge method regularly where tonnage is too small to justify a cupola and close control of an exceptional grade of iron is required. Under such combination of circumstances there seems to exist a limited economical field for the complete cycle of melting, refining and superheating in the electric furnace.

Several of these "cold charge" furnaces are operating with acid hearth, which means leaving from the cycle the element of refining except in a sense that is mild in comparison with the rigorous basic process. Properly conducted, this acid process consists of melting and superheating under conditions that at least are non-oxidizing as far as furnace atmosphere concerns. The length of stay in the furnace after being melted may become a period of purification, insomuch as an undisturbed exposure to a high temperature in a harmless atmosphere is likely to bring about a flotation on the bath of some of its non-metallic inclusions. Especially will high sulphur aided by manganese automatically reduce in this way to a measurable degree. Irons with 0.15 per cent sulphur have been known to decrease by as much as one-fourth or one-third through manganese sulphide floating to the surface.

The cold-charge process for cast iron probably never will acquire more than a scattered application, and the greatest possibilities seem to lie with the duplexing process. This is because the cupola cannot be relegated to disuse without working economic violence to the commercial foundry. The cupola delivers molten iron, with a minimum of care and labor, too cheaply to be discarded. Any melting scheme for the iron foundry must take into serious consideration the cupola furnace. It needs no substitute, but at times an adjunct is desirable; here is the opportunity for the electric furnace.

Since the duplexing process apportions refining to the electric furnace, the most logical hearth for the electric furnace is the most potently refining one—in other words, the basic hearth. In it lie the best and widest possibilities of the electric furnace for cast iron.

Duplexing in Basic Hearth

Duplexing, as said before, probably was practiced first at the Cincinnati plant, and there also it has been used most continuously, while it was at a plant in Birmingham, Ala., that it developed its greatest tonnage where a pipe foundry frequently passed over 200 tons of iron through the electric furnace in 24 hours.

"What are the conditions in the average iron foundry of today that make feasible the addition of an electric furnace to the equipment? This is a common question. In a sentence we can answer that the influencing factors are, (*a*) the limitations of the cupola, (*b*) the cost of available raw materials, and (*c*) a shifting of the basis of competition in a certain volume of the gray iron castings business from price per pound to quality per piece. Any one of these may carry enough weight to swing the balances in favor of the electric furnace in some cases, while in others—by far the great majority—the united three cannot budge the foundry policy from its present established position. The electric furnace must not be taken up hastily and without a complete survey of its advantages and disadvantages because in one field it may be an unmistakable success while in another it will show only loss.

Advantages of Cupola Melting

In speaking of the limitations of the cupola the writer must not be taken as unfriendly to it or in the least unappreciative of its many sterling virtues. It is without peer as an efficient, inexpensive, universally operated metallurgical servant for the production of molten iron. Probably no other furnace can melt similar metal at a fuel cost of 75c. or lower per ton, which is what the cupola does steadily and with approximate satisfaction on all counts. It lacks only some of the refinements of operation frequently demanded by modern conditions. These occasionally demanded improvements are an ability to reproduce uniformly any desired composition of iron, a positive ability to refine in addi-

*A paper presented at the forty-first general meeting of the American Electrochemical Society held in Baltimore, Md., April 27, 28 and 29, 1922.

ion to melting and an increased power to superheat. To accomplish refining the cupola is helpless, while it has decided restrictions when it comes to superheating.

Just as the inability to refine and superheat are outstanding weaknesses of the cupola, so is the corresponding ability to do them the great advantage of the electric furnace, especially the furnace with basic bottom. Such furnace is the pre-eminent refining furnace for iron and steel. Handling cast iron, it is capable of delivering without too great attention metal superheated to any degree, reduced in sulphur as required, deoxidized and with carbon, silicon and manganese adjusted to the desired standards. Phosphorus alone cannot be altered in cast iron by the electric furnace except by impracticable methods.

The electric furnace is at its best when coupled with a chemical laboratory in an intimate manner. By sampling the molten iron as soon as transferred from the cupola the laboratory can determine as many elements as desired, and the proper additions can be made before the metal is ready to pour, making possible the closest regulation of the composition. Especially is this valuable in regulating silicon and carbon, elements reflected in the machinability of the castings. The rapidly growing tendency in machine shops to introduce standardized rates of machining seems to be taking little or no heed of the fact that there are many kinds of cast iron and that more than one kind may come from one foundry in one cupola during one day.

Maintaining fixed rates of machining and high production cannot be divorced from a parallel preserving the fixed proper grade of iron in the castings. In order to keep uniformly a certain machinability, iron must not vary in composition over too wide a range, especially in silicon and carbon, and at times manganese. Not a few modern factories have installed ultra-modern castings-finishing methods without first co-ordinating in the proper way their metallurgical and mechanical operations. In such cases the results are likely to be either a sad falling down in production from what was so elaborately planned, or a sacrifice of highly desirable physical properties in the product in order to attain and preserve production. Planning production without first establishing the best grade of iron for the product has led to more than one manufacturing débâcle.

Desulphurization

The most striking reaction taking place in the basic electric furnace is desulphurization; also it may become its most valuable. There is no gainsaying that there is a tendency toward higher sulphur in the world's scrap pile. This is not because the foundrymen are no longer afraid of it and are giving it free rein, but rather because it daily is becoming more difficult to hold it within bounds. The universal scrap pile is swollen with the grim harvest of the greatest of wars, and economy demands that it be worked over into usable implements fit for the pursuits of peace. The average of the sulphur is high, perhaps 0.15 per cent, and upon remelting in the cupola almost 0.03 per cent more is picked up with each remelt. The basic-hearth electric furnace seems created almost for this crisis. Elimination of sulphur by its means is one of the readiest of metallurgical operations. Cast iron of 0.18 per cent can be reduced to under 0.07 per cent in about 30 minutes, meaning the changing of relatively bad iron into good. Geographical considerations are strong here, and the foundry located in a region remote from the sources of good pig iron, and therefore having to rely upon the scrap pile of the neighborhood, may be in a logical position to consider seriously the basic-hearth electric furnace.

Illustrating this application of the furnace, there was described in 1920 a small unit on the Pacific coast in which a hand-fed, two-phase arc furnace was utilized for working up otherwise unusable iron scrap.[1] Tensile strengths of 40,000 to 45,000 lb. to the square inch were claimed for the iron.

Sulphur Limits

The introduction of the basic-hearth electric furnace is largely responsible for the prominence that the subject of sulphur in cast iron, especially low sulphur as compared with high, has received in recent years. The time is approaching rapidly when the question of the real effect of various amounts of sulphur in cast iron must be systematically and authoritatively investigated. Something is needed to reconcile the apparently anomalous results with high- and low-sulphur irons that are reported from time to time by different foundrymen and metallurgists. Logical sponsors for such inquiry would seem to be either the American Society for Testing Materials or the American Foundrymen's Association, or a committee of the two organizations.

The conditions in cast iron that will conduce to the precipitation of sulphide, in particles of an optimum size and of an optimum degree of dispersion, so as to assist or at least not hinder the production of mechanical properties of a high order, is a subject about which we know practically nothing. In conducting a research along this line we can suggest a very promising means of attack in the recently announced slip interference theory of the hardening of metals by Jeffries and Archer,[2] which seems capable of a wide application to many of our metallurgical problems, including the one of sulphur in iron. The question of mechanical tests also is involved in the solution of the sulphur problem, and it seems advisable that increased attention be given to tests of a more dynamic nature than the customary transverse and tensile tests, because there is good reason for believing that tests of such nature will differentiate between irons that give nearly identical results under the mentioned static tests.

If an answer to the sulphur problem ever is found, it probably will be many-fold with different limits of sulphur for different kinds of castings. The writer has first-hand knowledge of one class of large castings that invariably are "dirty," to quote the foundryman, at an important machined point whenever sulphur reaches 0.10 per cent or over. Empirically in this one case the answer has been found; generally we can only surmise how far we dare go with sulphur.

To the writer it seems that the sulphur question is involved in the greater one of general refinement, and it is probable that iron high in sulphur also is endowed plenteously with other impurities, some of which may be almost entirely unknown. Examples are oxygen in various combinations, nitrogen as nitride and perhaps others even less familiar. The fact that an iron is desulphurized is evidenced that it has passed through a

---

[2] "The Slip Interference Theory of the Hardening of Metals," Zay Jeffries and R. S. Archer, CHEM. & MET. ENG., 1921, vol. 24, p. 1057.

strong refining treatment, and the possibility that some of the benefits attributed to low sulphur in reality may be the result of the removal of one or more other impurities along with it has to be recognized. Desulphurization of iron means one of the most drastic cleansings known to metallurgy, and consequently low sulphur is becoming a hall-mark of refinement.

Refining Reactions

Removal of sulphur requires a reducing slag, and this carries with it additional advantages to the iron. Broadly speaking, there are two inflexible requirements to be complied with before desulphurization can take place—a strongly basic slag and complete deoxidation of slag and bath. Without both there is no elimination of sulphur. The slag is made from an excess of lime, with fluorspar added for fusibility, and coke dust to produce the needed reducing conditions. Deoxidation of bath, since manganese, silicon and carbon all are present, perhaps is a somewhat complex reaction, but for simplicity we can assume the probable rôle of manganese as illustrative:

$$FeO + Mn = MnO + Fe$$

Being not as soluble in molten iron as FeO, the MnO rises to the surface to be taken up by the slag, where it is acted upon by the carbon and reduced back to metallic manganese, the carbon monoxide escaping. After the last of the oxide has been removed from the slag the first step toward desulphurization begins. Immediately around the electrodes where the greatest temperature prevails the carbon and the lime of the slag react, forming calcium carbide. This reaction is assurance that deoxidation is completed. Elimination of sulphur then proceeds by one or probably both of the following reactions (where Fe may act interchangeably with Mn):

$$MnS + CaO + C = Mn + CaS + CO$$

$$3MnS + 2CaO + CaC_2 = 3Mn + 3CaS + 2CO$$

The calcium sulphide formed in either reaction is insoluble in molten iron.

Effect of Oxygen in Cast Iron

Deoxidation we have seen is a necessary concomitant of desulphurization, and cast iron coming from this process should be fairly free from oxides. This introduces one of the moot questions of cast iron. By some reputable authorities it is stoutly maintained that molten cast iron contains too much carbon, silicon and manganese to be able to carry iron oxide at the same time. Others declare it is entirely possible, and that its presence has certain tangible effects. As to the nature of the effects again there is a division of opinion. One group claims they are good, while another takes the opposite view, roundly condemning oxidized or "oxygenated" iron. The writer inclines to the belief that oxygen often persists in cast iron, in spite of the presence of oxidizable elements that should remove it, and also that its presence is undesirable. It seems to him that the persistence of oxygen as iron oxide in molten iron is as reasonably expected as is the well-known persistence of determinable amounts of sulphur and phosphorus in steel heats that have been put through the most rigorous and theoretically impeccable treatments for their removal. It is readily explained by the law of mass action, which enables the iron to hold to the last traces of these impurities.

That the influence of oxygen on the whole is bad is borne out by many experiences with the product of badly acting or carelessly operated cupolas. In these cases the iron without doubt was exposed to oxidizing conditions, and that it was materially affected thereby was shown in the sluggishness of the melt, which in spite of a high temperature prevented its running out castings solid enough to pass a porosity test. It appears probable that oxygen in some of its combinations, especially iron oxide, raises the freezing point of cast iron, bringing about a practical diminution of fluidity. One other point against iron oxide is its reaction with carbon, which is known to produce unsoundness in steel through the resultant gas, and there is reason to hold that this can happen also with cast iron. The time spent in the electric furnace during duplexing gives ample opportunity for this reaction to complete itself.

The oxygen question of cast iron is bound to remain unsettled as far as universal conviction is concerned, until analytical chemistry rises to the occasion. At present there is no generally accepted adequate method for determining all the oxygen in iron or steel. The Ledebur method is practiced here and there, but admittedly has serious limitations, it being claimed that it reaches at best only 75 per cent of the ferrous oxide that may be present,[3] while it misses entirely the oxides of manganese, silicon and titanium. Few contributions to metallurgy could at present be greater than a complete set of accurate practicable methods for determining oxygen and oxides in the various metals and alloys. Let those analytical chemists who feel that dull and futureless is their lot ponder this opportunity for making a well-nigh monumental contribution to practical metallurgy! In the same category we may also include nitrogen and other gaseous elements. The arc electric furnace, particularly the long-arc furnace, with its seeming possibilities for nitrogen fixation, makes pertinent the question of determining nitrogen readily and studying its effects upon iron and steel. There are the Allen method, and one or two others, for determining nitrogen, but they are attended by an uncertainty similar to that of the Ledebur oxygen method.[4]

We are forced to admit that chemical analyses as now made of metals and alloys often are only part analyses, and the elements that are eluding the analyst may be of paramount practical importance.

Advantages of Superheat

In no other furnace can superheating be so effectively done as in the electric furnace. Either the acid or the basic furnace is a good superheater, but the former has some disadvantage in that too high superheat sometimes (depending considerably upon the quality of refractories) has a tendency to raise the silicon unduly. Several times the writer has seen as high as 3.80 per cent silicon in cast iron coming from an acid furnace that went in at barely 2 per cent. In the basic furnace the tendency is toward a slight reduction.

The advantages of superheating can all be summed up in the one word "fluidity." The electric furnace gives fluidity to irons not commonly considered fluid, a conspicuous example of which is low-phosphorus iron. This class of irons generally is preeminently strong, but

[3] Bureau of Standards Scientific Paper 346, by Cain and Pettijohn.

[4] Very recently (Chem. & Met. Eng., 1922, vol. 26, p. 218) there was published an iodide-iodate method by Hurum and Fay, that may be one of the needed long steps forward in the determination of nitrogen in steel; so far no mention has been made of its applicability to cast iron.

nsuited for castings needing fluidity. Superheating in he electric furnace can make many of these irons ligible for the thinnest of sections.

Fluidity is a strong assurance of solid castings hrough freedom from blow-holes, shrink holes, slag nclusions and the like. Superheated metal increases he effectiveness of risers by lengthening the period of uidity, which is their only period of activity as feed-rs, and thereby obviates to a large degree that internal hrinkage that comes from fluid contraction of the ietal. Abetted by superhot metal, the efficiency of the rdinary riser becomes surprising.

Blow-holes seem to be eliminated to a considerable xtent by superheated metal acting through risers. The errostatic pressure of molten iron is nearly one-quarter f a pound per square inch for each inch of head. In ny mold of ordinary dimensions this is not great nough to increase perceptibly the density of the metal tself, but it seems sufficient to prevent the release of issolved gases from the metal and the consequent ormation of blow-holes. In this way the pressure of uid molten metal may be said to increase the actual ensity of the castings themselves by the elimination f blow-holes. This tendency of very fluid iron to pre-ent by pressure the liberation of dissolved gases per-aps is somewhat unnecessary in the cases of electric urnace irons that have been through sufficient refining o insure practical degasification.

Carbon Oxides in Solution

In connection with the gases CO and CO_2 held by he metal in solution or otherwise, there was a sig-ificant paper read before the Iron and Steel Institute British) in the autumn of 1920,[5] by Honda and Murakami, in which it was claimed that in pure iron-arbon alloys graphite is formed not as the direct result f the decomposition of cementite at high temperature ccording to the reaction, $Fe_3C = 3Fe + C$, but rather hrough the catalytic action of CO or CO_2. Should this old true with impure alloys such as cast iron, the emoval of these gases in the electric furnace might e expected to have a retarding effect upon the precip-tation of graphite.

The present writer has seen some evidence to trengthen this theory, chief of which is an occasionally pparent capability of electric-furnace cast iron to arry higher silicon without perceptible opening of the rain, excessive graphitization and the consequent oftening and loss of strength, than a similar iron is apable of that has not been refined. In other words, legasification in so far as the elimination of CO and CO_2 is concerned may explain a part of the increased trength and soundness of electric furnace cast iron, on he ground of its ability to discourage a headlong mas-ive precipitation of graphite. It may be that this retard-ng influence modifies the form of the graphite as well s influencing finer and more advantageously dispersed articles. This is far from a settled matter and the nain object in introducing the idea is to stimulate hought and perhaps point out a path for investigators o explore.

To conclude, it may be that the electric furnace never vill acquire the widespread use for cast iron that its nost enthusiastic friends predict and desire, yet the vriter of this paper does not feel that its usefulness to he art of iron founding is to be measured solely by its number of installations. If it accomplishes nothing more than to inspire a new and fruitful interest in the many problems of cast iron, it may well be said to have been a generous benefactor to all branches of the art. Not only does the electric furnace open up new avenues for the production of cast iron but also new lines for thought and experiment, and who is the man to declare that this last is least in importance?

Distribution of Tar Recovery From Byproduct Coke-Oven Gas

By Frederick M. Washburn and George E. Muns

At the byproduct coke plant of the Wisconsin Steel Works, located at South Chicago, Ill., an investigation was made into the quantity and composition of the tar removed at various points along the path of the gas, resulting in the data given below.

The plant consists of two batteries, each of forty-four Wilputte ovens, together with complete direct type byproduct recovery apparatus. The gas is conducted by goosenecks from the top of the oven through a mushroom valve and into the collecting main. At the mushroom valve it meets a spray of flushing liquor, which prevents pitching of the valve seats. The gas is then drawn through the suction mains, where it is again

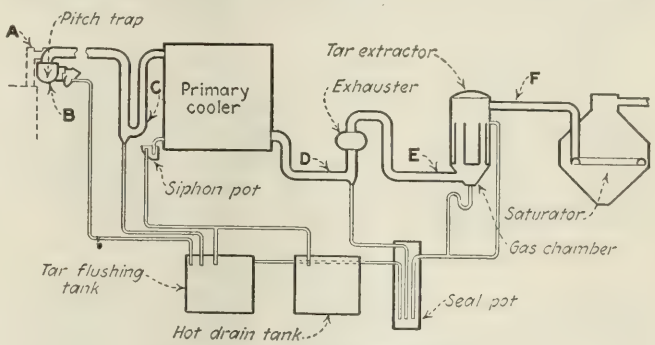

FIG. 1—GAS FLOW CHART

sprayed with flushing liquor, and conducted to the primary coolers, which are of standard indirect type, water-tube design. From this point it passes through Root positive exhausters, which force it through the tar extractor and other apparatus for the recovery of byproducts.

Fig. 1 shows diagrammatically the flow of gas from the ovens through the gas mains and apparatus, and the points at which condensed or extracted tar is drawn off for subsequent separation and storage. Temperature and pressure conditions at the points designated in the figure by the letters *A* to *F* are given in Table I.

TABLE I—TEMPERATURES AND PRESSURES THROUGH SYSTEM

Readings at	Temperature Deg. C.	Pressure	Readings at	Temperature Deg. C.	Pressure
A	346.0	3 mm.	D	26.0	—4.9 in.
B	176.0	3 mm.	E	36.1	63.7 in.
C	79.5	—3.1 in.	F	35.5	55.8 in.

All tests were run under uniform operating conditions, with temperatures and pressures normal, with an average net coking time of 22 hours, 51 minutes, and with a coal mixture of 95 per cent Benham (high-volatile) and 5 per cent Pocahontas (low-volatile) coal. Average tar and gas yields per ton of dry coal charged were taken over a period of 24 days operating at this

coking time, and amounted to 11.39 gal. of tar and 11.365 cu.ft. of gas. All figures in tar gallonage are calculated on a moisture-free basis because of the wide variation in moisture content of different tars separated.

The general plan of the test was actually to measure the tar recovered at the different points for a definite period of time, noting the total volume of gas handled during that time and obtaining a representative sample for analysis of the tar produced. Lack of tank space made the actual running time of the tests shorter than was expected, but good checks were obtained by repeating. In detail, the procedure was as follows:

Test A. Tar Extractors

The hot drain tank was isolated and the tar separated by the P. & A.'s discharged this tank. Measurements were made at the start and finish of each run, and gallonage determined from the tank calibration and measurements. The sample for analysis was taken from the seal pot overflow.

Test B. Gas Chamber (After Exhauster)

The gas chamber was emptied at the start. During the run the condensate was drained into tarred barrels at regular intervals, and at the finish of the run. The gallonage was determined from the weight and specific gravity of the tar. The sample for analysis was taken from the barrels.

Test C. Exhauster Drain (Suction Side)

The exhauster drains were sealed off in 500-gal. cylindrical tubs, which were measured at start and finish of run, and the gallonage determined by calibration and measurements. The samples for analysis were taken from the tubs.

Test D. Primary Coolers

The drains from the primary coolers were discharged into the isolated hot drain tank, which was measured at the start and finish of the run. The gallonage was determined by the tank measurements and calibration. The samples for analysis were taken at the siphon pot.

Test E. Suction and Collecting Mains

This tar occurred in small quantities in comparatively large quantities of liquor and owing to the difficulty of measurement the amount of tar separated here was obtained by the difference between the previous tests and the total production. Separate samples for analysis were taken from the suction and collecting mains. In order to obtain an uncontaminated sample, an all-liquor flush was circulated for 4 hours before the test and during the test.

Moisture determinations were made on all samples except those from the suction and collecting mains. All samples were dehydrated, and specific gravity, free carbon and distillation determinations made on the dehydrated tars. The specific gravity determinations were made with a Westphal balance with the exception of the samples from the suction and collecting mains, which were too viscous for this method, so a tar specific gravity bottle was used. The distillations were made on a 100-c.c. sample in a 200-c.c. side-neck distillation flask connected to a vertical condenser.

The tar obtained from the exhauster drains (test C) probably represents separated tar mechanically carried over from the primary coolers, as from Table III

TABLE II—DISTRIBUTION OF TAR

Test	Location	Duration of Run, Min.	Gas Passed, Thous. Cu.Ft.	Tar Obtained, Gal	Tar per Thous. Cu.Ft. of Gas, Gal.	Percentage of Total Tar Production
A	P. & A. tar extractor	325	2,451.5	179.63	0.0732	7.30
B	Gas chamber	325	2,451.5	49.50	0.0202	2.01
C	Exhauster	325	2,451.5	433.26	0.1767	17.64
D	Primary cooler	120	867.5	354.96	0.4092	40.84
E	Suction main					
F	Collecting main	...	.....	.....	0.3227	32.21

it may be seen that samples C and D are very similar in composition. Sample C is a slightly lighter tar than sample D, which would naturally follow, since sample D is composed of tar separated in all sections of the primary coolers, while sample C probably consists mainly of tar from the last or coldest section. From Table II it may then be seen that over 90 per cent of the tar present in the gas is removed during its passage through the mains and primary coolers. Two per cent of the remaining tar is removed by passage through the exhauster, leaving only a little over 7 per cent to be removed by the tar extractor. The free carbon and residues on samples E and F are extremely high due to coal dust mechanically carried over from the ovens. This coal dust is subsequently removed in a pitch trap. The tar from tests E and F are very heavy and viscous, since they were separated at a high temperature. As the separation temperature is lowered the tars become lighter and more fluid. Due to the increase in pressure and temperature caused by passage through the exhauster, a heavier tar is separated from the gas chamber (test B). Up to this point the separation of tar has been governed mainly by temperature and pres-

TABLE III—ANALYSIS OF TAR

Test	Moisture	Sp. Gr. at 1.5 deg. C. 15.5	Free Carbon	Under 110 Deg. C	110 to 170 Deg.	170 to 235 Deg.	235 to 270 Deg.	270 to 300 Deg.	Residue and Loss
A	4.45	1.135	4.21	1.5	6.0	39.5	9.5	6.5	37.0
B	.47	1.140	3.45	1.0	3.0	30.0	10.5	5.5	50.0
C	6.50	1.121	3.44	1.5	5.5	33.0	10.0	8.0	42.0
D	5.60	1.140	3.48	.5	5.0	35.5	11.0	6.0	42.0

F	....	1.202	10.92	...	...	5.0	6.0	7.0	82.0

sure conditions, but in the P. & A. tar extractor the temperature and pressure cease to play such an important part, for the mechanical action of the impingement of the gas on a surface caused the separation. The tar separated from the tar extractor (test A) represents practically the last traces of tar in the gas and is the tar having the greatest percentage of oils and least pitch residue of any of the tars tested.

Carbonization of Peat

Carbonization and gasification of peat are very fully discussed in a report of the Commission of Inquiry into the Resources and Industries of Ireland. This document which is available from the offices of the Commission 87 Grafton Street, Dublin, for 2s. 9d., discusses very fully the resources of that country and the methods of development which have been tried. However, it is not by any means limited to the technology which has been utilized there, but gives a very complete analysis of the work done in all parts of the world.

In view of the comprehensive nature of this report it is not possible to do it justice in a brief review. Anyone interested in the subject of peat utilization will find it very desirable to secure a copy of the full document.

Concentrating Dilute Nitric Acid Solutions*

A Study of Rate of Concentration — Application of Results to Fractionation — Determination of Composition of Vapor Above Boiling Solution of Known Composition

By Clifford D. Carpenter and Joseph Babor

THE PROBLEM of concentrating dilute solutions of nitric acid may be conveniently divided into two stages, preconcentrating and superconcentrating, *i.e.*, bringing the acid up to 50 or 60 per cent by simple fractionation and making acids of higher concentration which requires some special process.

This report will deal only with the problem of preconcentrating. Work is in progress on the problem of superconcentrating and the results will be reported at a later time. For our own convenience in describing our work and discussing the application of the results, we will divide the report into two parts. The first will give our results and discuss them in relation to concentrating the dilute acid by simple distillation and by fractionation.

Part I

Analytical Methods Used

In a recent article[1] we described a method by which we were able to distil a solution in such a manner as to prevent all errors introduced by fractionation and therefore study the rate of change in the concentration of the boiling solution while removing a vapor which was continuously in equilibrium with the boiling solution. While making more extended experiments we found ourselves in trouble on duplicating our results. We found our method of standardizing the base (succinic acid) was not easily duplicated so we tried the thallate and benzoic acid methods which checked each other but did not check the value given by the succinic acid method. We then secured from the Bureau of Standards a sample of benzoic acid with which the base used in these experiments was standardized. We have made a much more extended study of the problem using the experimental procedure described in our first article.

The Tables I to VI give the results obtained and Fig. 1 gives these results expressed graphically. The upper curve of Fig. 2 is a composite expression for the rate of change in the concentration of 1,000 grams of a 5 per cent acid from 5 to 68 per cent. The points

which define this line are obtained from the results given in the six tables and are given in Table VII. The lower curve in Fig. 2 is a composite expression for the rate, in grams, at which the same acid escapes in the vapor while the concentration of the boiling acid changes from 5 to 68 per cent. If we read the points, in terms of the left-hand ordinate, at which the upper curve intersects the vertical lines representing the composition of the boiling solution we have the amount of distillate. If we read the points, in terms of the right-hand ordinate, at which the same line intersects the lower curve we have the amount of acid which is in the distillate. These points give the results in Table VIII.

An examination of Figs. 1 and 2 shows that very little acid is lost in the distillate until the concentration of the boiling solution reaches 20 per cent (1.6 g. acid to 759 g. distillate). The rate of loss increases slowly until about 30 per cent (2.4 g. acid to 809 g. distillate) when the rate becomes much greater but remains

TABLE VIII—INTERPRETATION OF FIG. 2.

Change in Composition of Boiling Solution from 5 per cent to	Grams of Distillate	Grams Acid In Distillate	Change in Composition of Boiling Solution from 5 per cent to	Grams of Distillate	Grams Acid In Distillate
10 per cent	505.0	0.5	40 per cent	892.5	7.07
15 per cent	670.0	0.95	45 per cent	910.0	9.75
20 per cent	758.0	1.60	50 per cent	926.5	13.25
25 per cent	810.0	2.40	55 per cent	941.3	17.75
30 per cent	845.0	3.55	60 per cent	956.7	24.10
35 per cent	871.5	5.05	65 per cent	977.0	35.20

rather regular until about 55 per cent when it again begins to increase more rapidly. At 63 or 64 per cent there seems to be a striking change and the concentration of the vapor approaches that of the residue very rapidly. It is possible that the peculiar inflexion in the curve between 63 and 64 per cent can be accounted for by assuming the presence of $2(H_2O)HNO_3$. The curve shows that the rate of change is regular enough to permit efficient fractionation up to a 55 or 60 per cent acid.

Galle[2] recently studied the preconcentration of nitric acid by using a flask to which was sealed a fractionating column and as a result of his experiments advises

[2] *Z. Angew. Chem.*, 1921, vol. 34, pp. 168 to 170; 173 to 175.

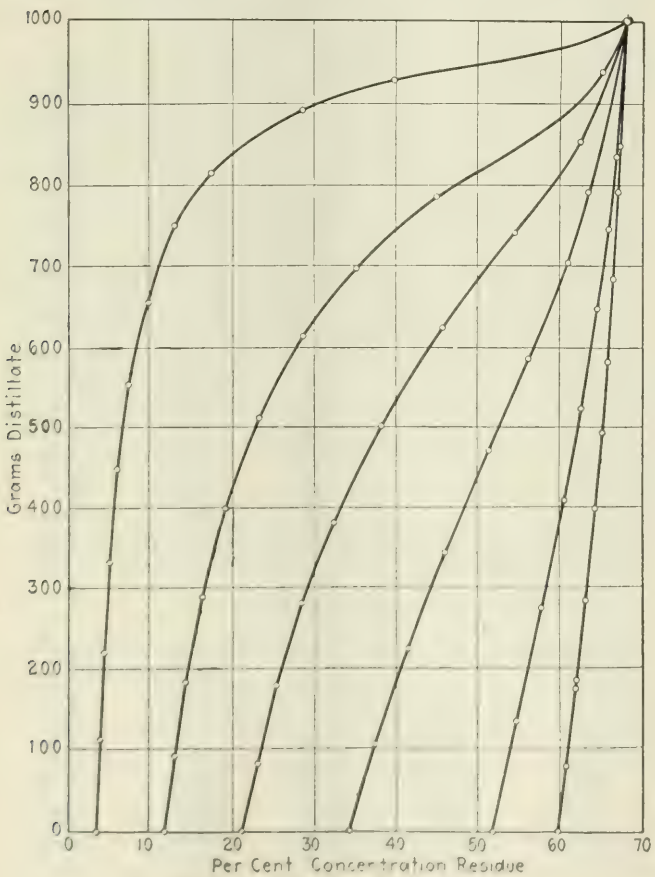

FIG. 1

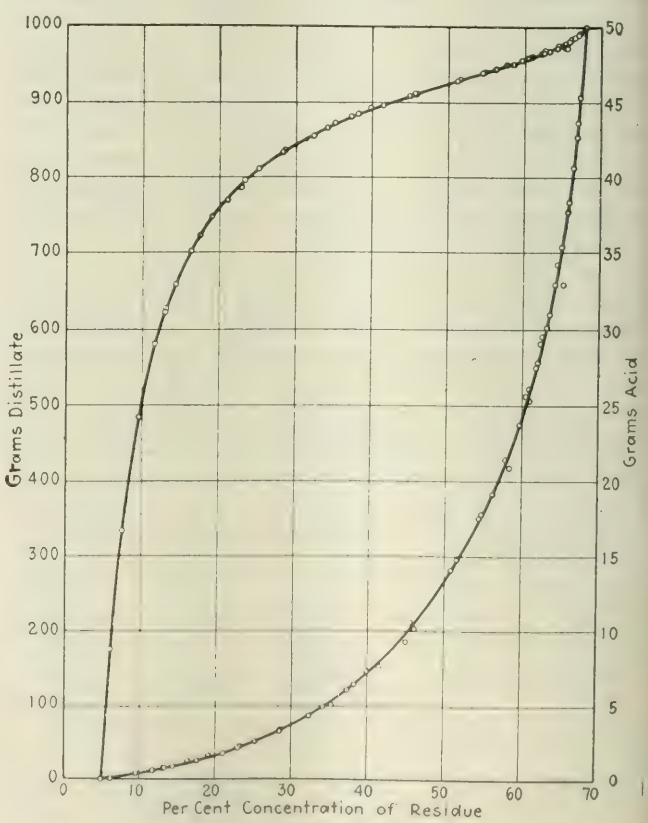

FIG. 2

the fractionation of dilute acid solutions up to 65 per cent before employing methods for superconcentrating the acid. It is evident however that the efficiency of fractionation will be much less above a 55 to 60 per cent composition.

If we wish to obtain a 55 per cent acid from 1,000 g. of a 20 per cent acid by simple distillation, the first residue will be 242.6 g., containing 133.4 g. of the original 200 g. of acid. The first distillate of 757.4 g. will contain the other 66.6 g. of acid and will have a composition of about 8.8 per cent acid. A distillation of the first distillate will produce 78.7 g. of a 55 per cent acid containing 43.3 g. of acid and give a second distillate of 678.7 g. with a composition of about 3.4 per cent. This means by two distillations requiring the vaporization of 1,336 g. of dilute acid that 321.3 g. of 55 per cent acid can be obtained from 1,000 g. of 20 per cent acid, a recovery of about 177 g. or nearly 90 per cent of the 200 g. of acid in the original 20 per cent solution. If a third distillation is made, about 15 g. more of acid may be recovered as 55 per cent acid and about 650 g. of 1 per cent distillate removed. This means that in three fractionations requiring the vaporization of about 1,985 g. of dilute acid that about 92 per cent of the original acid may be recovered as 55 per cent acid.

If it were desired to obtain a 65 per cent acid from the 20 per cent acid, the first distillate removed would be 905 g. containing 138.25 g. of acid while there would remain 95 g. of 65 per cent acid. The second distillation would begin with 905 g. of little more than 15 per cent acid and would require the removal of 840 g. of distillate leaving 65 g. more of 65 per cent acid. Two distillations of a 20 per cent acid will give 160 g. of 65 per cent acid by vaporizing, 1,745 g. of dilute acid. This means a recovery of 104 g. of the original 200 g. of acid. In order to recover 90 per cent of the acid from a 20 per cent solution as 65 per cent acid many fractionations would be required.

From our data it becomes a simple matter to calculate the number of fractionations required to recover nitric acid from dilute solutions at a higher concentration.

Part II

Composition of the Vapor

If we take the curves given in Figs. 1 and 2 and plot them on large co-ordinate paper it will be quite easy to read the amount of distillate and the amount of acid in the distillate while the strength of the acid changes one per cent from any desired concentration to the next higher. Knowing from the data given in Tables I to VI the rate at which the distillate is increasing, a very close estimate can be made for the composition of the vapor of the boiling solution at a concentration represented by the mean composition. Such calculations have been made by reading the values from the curves and the results are given in columns headed C and B in Table IX and have been used to define the curve given in Fig. 4.

Recently Pascal[3] and Berl and Samtleben[4] have carried out experiments in order to determine the composition of vapor above a boiling solution of nitric acid of known concentration. Both used an air bath heated by means of a bunsen burner. They inclosed the flask containing the boiling liquid in the air bath in order to

prevent condensation in the upper part of the flask and delivery tube. Fig. 3, a, gives a sketch of our apparatus, described in our recent paper,[1] and the ones used by those referred to above. In the case of Pascal, Fig. 3, b, two thermometers are suspended, while Berl and Samtleben, Fig. 3, c, used only one. We have left out the thermometer as it would act as a fractionation column. The only way in which heat can be transmitted to it is by conductance from the boiling liquid and through the vapor. This fractionating effect would be very small in the more dilute solutions but as the concentration increases such an error becomes more serious, especially at the points where the change is most rapid. In our method it would be very serious for any such error becomes cumulative. If, however, it is only desired to know the composition of a vapor above a boiling acid, the error due to fractionation on a thermometer could be made negligible compared with the experimental accuracy possible by taking a small fraction from a large amount of boiling acid. Berl and Samtleben did this and their results are given in the second column in Table IX and are indicated in Fig. 4 by circles to which are attached small arrows. Those falling directly on our curve are indicated by two arrows and those falling to one side by one arrow pointing in the direction indicating the side upon which the point falls. They have made a slight error in their

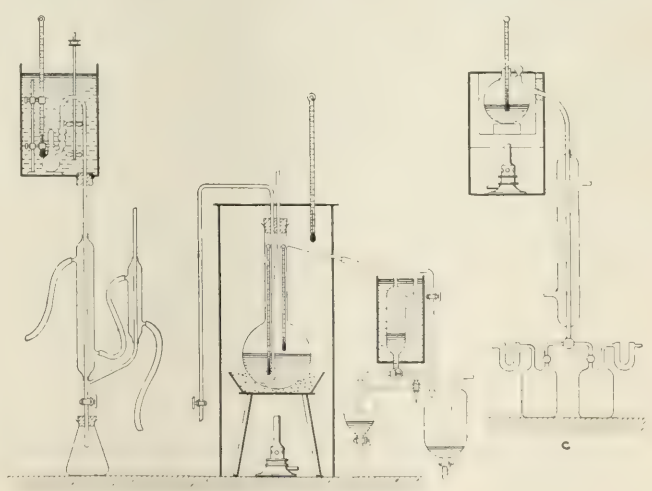

FIG. 3

[3] *Ann. chim.*, 1921. New series, vol. 15, pp. 253 to 290.
[4] *Z. Angew. Chem.*, 1922, vol. 35, p. 201.

estimation of the composition of the vapor, however, for they assume the concentration of the distillate to be the composition of the vapor above a boiling acid which is the mean between the composition of the boiling acid at the beginning and at the end of the change which takes place while the distillate is being collected. It is evident from the shape of the curve in Fig. 2 that this could only be approximately true for the lower concentrations of acids. They have partly corrected the error in this assumption by taking small fractions in the higher concentrations which of course results in a larger experimental error in determining the amount of acid in a small fraction.

Take for example their values obtained for 31.75 per cent (obtained by assuming the concentration of the distillate, 4.94 per cent, while the boiling acid changes from 30.22 per cent to 33.28 per cent to be the composition of the vapor of the mean concentration 31.75 per cent); for 37.99 per cent (residue changing from 37.13 to 38.85 per cent, the distillate of which was 9.20 per cent acid); for 43.50 per cent (residue changing from 42.73 to 44.27 per cent, the distillate of which was 14.86 per cent) and for 47.77 per cent (residue changing from 45.57 to 49.96 per cent, the distillate of which was 21.71 per cent), and note their position in Fig. 4. These values all fall to the right of the curve for in this range the concentration is changing rapidly and the composition of the distillate represents the composition of the vapor for a lower concentration of boiling acid than obtained by taking a mean value. While the values are in close agreement with those given by us, most of the points fall to the right of our curve as would be expected.

Pascal has given the values obtained for five points and are given in column headed P in Table IX and indicated in Fig. 4 by small squares.

Conclusion

1. All values given in our first paper have been redetermined.

2. A brief discussion of the use of our results in considering the problem of fractional distillation has been given.

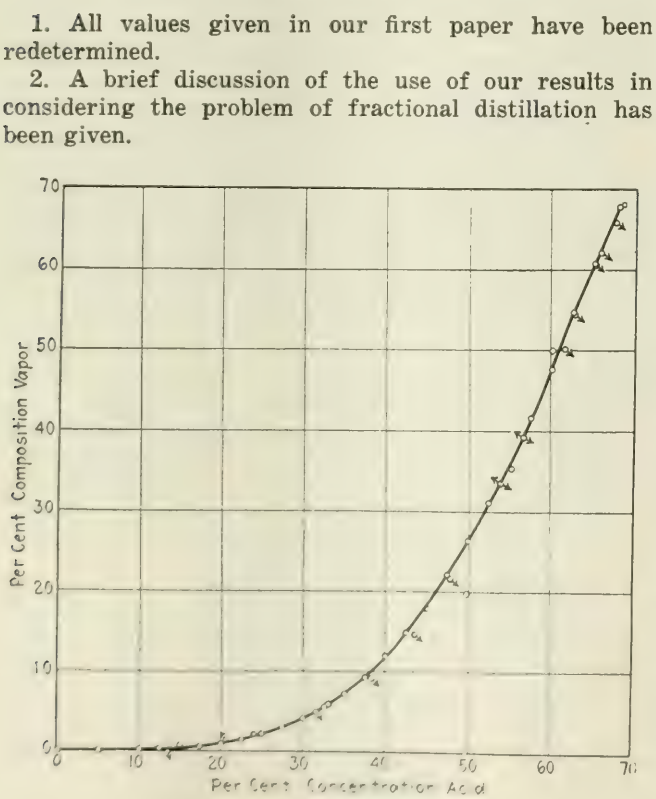

FIG. 4

3. The composition of the vapor above a boiling nitric acid solution from 5 per cent to 68 per cent composition has been determined.

4. A comparison has been made between our results and those obtained by Berl and Samtleben and by Pascal, and errors in their methods have been indicated.

5. When the rate at which the distillate is removed while the change in the concentration of a boiling acid solution is known it becomes a very simple matter to calculate the amount of distillate necessary to be removed by successive distillations in order to recover any desired amount of the acid at a higher concentration.

Italian Oil Activities

An indication of Italian interest in the exploration of the country's oil resources is reported by Consul Leon Dominian from Rome. The Minister of the Department of Agriculture recently made a visit to the oil fields of Ripi and San Giovanni Incarico along the boundary between the Provinces of Rome and Caserta. (Government mining bureaus in Italy are under the administrative jurisdiction of the Department of Agriculture.) According to press reports of the event the Minister assured the managers of the local exploration plants that they could rely on Government help in their work.

It appears that one of the plans of the mining department of the Ministry of Agriculture is to subdivide the Kingdom into zones, in each of which it is proposed to station a Government oil expert. It is also proposed that the State purchase drilling plants specially adapted to deep boring, and that practical instruction in drilling be given to young mechanics prior to their employment by private concerns.

The region visited by the Minister of Agriculture is the seat of several exploration borings, two of which have already yielded oil. The depth at which oil has been found in that region varies between 147 and 240 meters (482 and 787 feet) and the total quantity of oil extracted amounts to 2 tons daily. It is proposed to carry on two sets of operations in the region for the purpose of tapping simultaneously the oil lying at shallow and excessive depths.

Another event which shows that attention is being paid by Italians to their native oil resources was the series of meetings of oil experts in Rome, beginning June 2, to discuss methods of increasing Italian oil production, particularly with reference to deep-seated oil resources. The experts recommended that oil explorations be conducted at great distance from one another in order that better knowledge of the country's possibilities be obtained, and that the Government should make a distinction between assistance to be granted to productive and unexplored regions. It was recommended that subsidies granted to productive zones should be confined only to exploration carried on beyond a depth of 600 meters in order that the deep-seated reserves, which are believed to be large, be tapped. Such subsidies are known as "premiums" in Italy and it is proposed to grant them on the basis of meters in depth.

Final recommendations were that capital intended for exploration work be exempt from all taxation, that no tax be imposed on the sales of native oil and that machinery imported from abroad for exploration work be allowed to enter Italy free of duty.

Petroleum Education

The Industry's Exacting Requirements of the Chemists and Chemical Engineers Are Carefully Analyzed and an Attempt Is Made to Outline Specialized Courses Most Likely to Yield Graduates With Proper Training and Preparation*

By Edwin DeBarr and Fred W. Padgett
University of Oklahoma

THE petroleum industry is one of very broad scope, involving various applications of physics, chemistry, geology, engineering and economics. The sequence of events has been concisely described as follows: The oil well is located by the aid of geology, drilled by the aid of profanity, the oil recovered and transported by the aid of mechanics, refined by the aid of chemistry, and the products are turned over to the shipping clerk. Those experienced in the oil business insist that the above description is mild and inadequate, especially in regard to drilling the well.

The petroleum geological engineer and the geologist are both primarily concerned with the problems of exploration and production. They investigate new areas for possibilities of production and are generally able to indicate whether or not the region is favorable for the accumulation of oil and gas. To the geological profession must go the credit for the discovery of quite a number of entirely new producing areas. Some time in the future, however, most of the exploratory work will have been completed, and the question arises as to whether or not geology will still bear its important relation to the industry. When this time comes, the petroleum geological engineer and the mining engineer will study in much more detail the structure and character of the producing formations and will focus their efforts on the problems of recovering the enormous quantities of oil which remain in the producing formations after they are considered to be exhausted. The results achieved in that field will probably be just as startling as those obtained during the period when new oil pools were being opened with almost monotonous regularity. The subject of valuation of established or prospective producing oil and gas properties is also one which the petroleum geological engineer has studied exhaustively and which often involves consideration of the previous history of adjacent or geologically related producing areas. Valuation has become very much a portion of the everyday work of the petroleum geological engineer and will also constitute an important part of his future work.

The Task for the Chemical Engineer

It is scarcely necessary to mention that applications of civil, electrical and particularly mechanical engineering are of fundamental importance wherever oil is being produced and transported or natural gas distributed, as well as in relation to problems of refinery design and construction. The chemical engineer is intimately concerned with several special phases of production, among which may be mentioned problems of emulsification and petroleum hydrology. Apparently the chemist or chemical engineer is well fitted for a fundamental insight into the character of crude oil emulsions, and therefore possesses a sound basis for undertaking investigations as to the most efficient method to be used in their resolution and the control of processes after being established. Petroleum hydrology is the chemistry of oil-well waters and has very practical significance. The character of oil-well waters differs in different fields, but generally has the same trend in composition among the formations in a single field. These facts may have practical application as indicating, from the analysis of water in the various horizons, when the producing formation is being approached during drilling. Furthermore, after the well is completed, and water happens to appear with the oil in more or less troublesome proportions, analyses or tests of this water may be of value in locating the horizon where the water originates, providing previous analyses or tests have been made at the different horizons where water is present.

The relation of the chemical engineer to petroleum refining is of fundamental importance. In the future, as in the past, the chemist and chemical engineer may be depended upon to make the discoveries which mark important advances in this phase of the industry. Who, it may be asked, if not the chemical engineer or the chemist, is qualified, from the standpoint of training, to make a truly fundamental study of the problems of distillation, refining, "compounding" and the recovery and utilization of byproducts, or intelligently to control processes already established?

Eliminating Waste

Important also is the problem of eliminating, wherever possible, the losses which occur. From the time the crude oil appears above ground until the finished products are obtained by refining, these losses occur, some of which may be wholly or partly eliminated. Important preventable losses often occur from evaporation during production and storage, and during refining from non-recovery of byproducts, inefficiencies in refining processes, leakage, evaporation, fire losses, etc. While the natural-gas phase of the petroleum industry has made commendable strides in recent years in regard to eliminating losses, there are still opportunities for preventing these during its transmission and distribution and while the product is being utilized. In no phase of the oil industry, however, will efficient operation, attention to details and elimination of loss and leakage give more tangible and immediate results than in that of natural-gas gasoline recovery. It is no unusual thing for an inefficient plant to be increased very materially in yield without change of design or the acquisition of new gas wells. At the refinery the oil must be taken as it comes from the pipe line, but in the natural-gas gasoline plant it is possible, and furthermore desirable, in order to obtain the best results, to give consideration to conditions in the field lines

*A paper presented in part at the Birmingham meeting of the American Chemical Society, April, 1922.

and even in the wells themselves, and thus to improve materially the quality and quantity of the gas obtained.

Developing New Industries

We are told that the peak of petroleum production is to be expected within a comparatively short time and that it will then become necessary to supplement the supply of petroleum from oil wells by production obtained artificially by the retorting of pyrobitumens such as lignite, coal and oil shale. Many of the problems that will develop in connection with this new industry will be peculiarly chemical. Before such an industry can be established on a commercial scale in this country, important problems of retorting, refining and recovery of byproducts must be solved. These problems are such as to attract the attention of the research chemist and chemical engineer, to stimulate his interest and will therefore result in productive research. After these problems are solved, the efficient control of the processes established will demand the best efforts of the chemical engineer.

It has been suggested, however, that this new industry in America will be in no sense a byproduct industry, but instead will develop along lines similar to the treatment of low-grade ore. In view of past experience and the fact that conservation can be made to pay its way, it would appear that the coming shale-oil industry will be comparable with the best practice in byproduct technology and that possible developments in refining of shale oil may result in recovery far surpassing in its variations that of the industry as now carried on in Scotland. Handling oil shale as low-grade ore is handled would probably ultimately result in such difficulties as many of the petroleum skimming plants of the mid-continent are now involved.

Petroleum Engineering Curricula

Taking everything into consideration, therefore, it is recognized that the chemist and chemical engineer have a fundamental place in the scheme of things in the bitumen industries, and this position is to become more important as the value of raw materials increases and as the economic necessities demand more efficient operation and attention to byproducts. This condition will no doubt then be reflected in a greater interest of universities in the subject of bitumenology. At the present time petroleum education is confined mainly to those universities the geographical location of which gives them special interest. In this connection may be mentioned the University of Pittsburgh, University of California, University of Oklahoma and the Colorado School of Mines. Dr. Roswell H. Johnson of the University of Pittsburgh was one of the first in this country to establish a course in petroleum engineering.

Problems in Outlining Courses

In establishing a curriculum in petroleum engineering, the following questions arise:

(1) Is it desirable to outline a course so that all the technical phases of the industry, including the principles of chemistry, physics, geology, engineering, economics and several special courses related to the oil industry are studied in a 4-year course; or

(2) (*a*) To outline a course as a whole so that the student completes in 4 years a course in petroleum chemical engineering which specializes in refining and where chemistry is made paramount; or

(*b*) To outline a 4-year course which is designated as petroleum geological engineering and stresses the study of geology; or

(3) To organize a 5- or 6-year course which shall be considered complete from the standpoint of chemistry, physics, geology, engineering and economics, equal attention being directed to both geology and chemistry.

A course according to this latter scheme would be ideal, and in addition to the more complete and better balanced training acquired would present greater opportunity for a thesis based on real research. On the other hand, the difficulty in connection with such a course would be that the bachelor's degree in most educational institutions can be acquired in 4 years, both in arts and sciences, and engineering.

Oklahoma's Course in Petroleum Technology

The writers are unable to understand how a complete course as outlined above, which includes the fundamentals of engineering besides those of chemistry, physics, geology and economics, can be completed in 4 years with equal stress being laid on both chemistry and geology. After all, the fundamentals really are the essentials, and when it is assumed that these have been acquired, it is then quite permissible to give special courses in petroleum technology. In the following paragraphs, courses in chemical petroleum technology are outlined which require as prerequisites university credits in general, qualitative, quantitative and organic chemistry and physics. These courses are open to all students of the university who can satisfy the requirements. Advanced organic chemistry, general physical chemistry and colloid chemistry are considered as important adjuncts to the work from the standpoint of chemistry. Titles of the individual courses in petroleum technology in the Department of Chemistry at the University of Oklahoma are as follows:

Chemistry 132. Petroleum and Natural Gas Technology. Lectures 3 hours a week during one semester.

Chemistry 137. Analysis of Petroleum and Petroleum Products. Laboratory 9 hours per week throughout one semester.

Chemistry 138. The Technology of Coal, Oil Shale and Asphalt. Lectures 3 hours a week during one semester.

Chemistry 139. The Analysis of Coal, Coal Tar, Oil Shale and Asphalt. Laboratory work 9 hours a week throughout one semester.

Chemistry 140. Lubrication, Lubricants, Liquid Fuels and Hydrocarbon Chemistry. Lectures 3 hours a week during one semester.

Chemistry 142. Gas Analysis. Laboratory 6 hours a week during one semester.

Chemistry 143. Petroleum Refining. Laboratory 6 hours a week during one semester.

Chemistry 144. Special Petroleum Products. Laboratory work 6 hours a week during one semester.

Chemistry 145. Field Work in Petroleum Technology. The testing of natural gas for natural-gas gasoline content, measurement of gas wells, testing of meters in the field and tank gaging and sampling. Equivalent to 6 hours of laboratory work a week during one semester.

Chemistry 146. Petroleum Research. Nine or fifteen hours laboratory a week during one semester.

In addition to the courses outlined above, there is listed a course in bitumenology for which elementary chemistry is the only prerequisite, and it is designed to meet the needs of students other than those majoring in chemistry.

Candidates for the degree of Bachelor of Science in Chemical Engineering at the University of Oklahoma may follow one of three lines of chemical engineering—viz., (1) Metallurgical chemistry, (2) petroleum technology (petroleum chemical engineering), (3) sanitary chemistry. It has been previously mentioned that the general course in petroleum technology (petroleum chemical engineering) includes the special courses in

etroleum technology outlined above, and some work in eology, besides the fundamentals of chemistry and ngineering. In connection with special petroleum ctures, it should be noted that the general course in etroleum technology includes a course in petroleum eology given in the Department of Geology, and a urse in the transportation of crude oil and the transission, measurement and compression of natural gas, the Department of Engineering, School of Mechanical ngineering. A title synopsis of the general course in etroleum technology (petroleum chemical engineering) llows for the sophomore, junior and senior years:

SECOND YEAR

First Semester. Quantitative analysis; Organic Chemistry lectures; General Metallurgy lectures; Calculus; and Physics.

Second Semester. Water analysis; Organic Preparations; Petroleum Technology lectures; Analysis of Petroleum and Petroleum products; Calculus; and Physics.

THIRD YEAR

First Semester. Physical Chemistry lectures; Geology; Applied Mechanics; Graphics; Thermodynamics; Mechanical Engineering laboratory.

Second Semester. Industrial Chemistry lectures; Physical Chemistry Laboratory; Gas analysis; Geology; Strength of Materials; Materials laboratory.

FOURTH YEAR

First Semester. Colloid Chemistry lectures; Petroleum Refining laboratory; Direct current machinery lectures; Economics lectures; Direct Current laboratory; Petroleum Geology; Technical English; Oil and Gas measuring and transmission and compression of natural gas.

Second Semester. Field work in Petroleum Technology; Alternating current lectures; Alternating current laboratory; Contracts; Accounting; Petroleum Research; Electives as follows: Chemistry 140 and 143, or Chemistry 138 and 139.

The special equipment for work in petroleum technology should include standard apparatus for the testing and analysis of the native bituminous substances nd their important products, as well as experimental pparatus for the processing of crude petroleum, aparatus for field work, retorts for low-temperature yrolysis of pyrobitumens, and apparatus for the manuacture of special products. At the University of klahoma the special equipment consists of an experiental refinery of 1-bbl. capacity, a low-temperature etort of about 20 to 25 lb. capacity, complete standard esting equipment and apparatus for field work.

CONCLUSIONS

It may be appropriate to inquire as to what a graduate in Petroleum Chemical Engineering should know, ide from the fundamentals of chemistry, engineering, ysics and economics, which, as most everyone will ree, are absolutely essential. The writers would like m to have a thorough understanding of the characteristics and peculiarities of the native bituminous subances; their physical and chemical properties; how test and differentiate them; how to refine them; and ally how to utilize them in their many applications. addition to this, is is desirable that he should have appreciation of the possibilities of research and to of such a frame of mind that too much is not taken r granted. Furthermore he must realize that there e some things which can be learned only by experice after his studies are completed.

The present paper has been an attempt to discuss the fferent aspects of petroleum education as based on the results of several years experience in an endeavor to establish suitable courses in chemical petroleum technology. In concluding this discussion the writers wish to state that they believe the future of this work to be most encouraging, especially in view of the interest shown in it both by chemists and by the oil companies which employ these men. A plan which has been suggested to the writers is that oil companies could profit by selecting promising men from the freshman or sophomore classes in universities and colleges, directing them to study along lines having a bearing upon the business, giving them summer employment, and then finding places for them in their organizations when they graduate, provided they meet their expectations. In fact this plan is already being followed, to some extent, by certain important oil companies.

Norman, Okla.

A New Electric Crane Truck

The Elwell-Parker Electric Co., of Cleveland, Ohio, has recently placed on the market the electric crane truck shown in the accompanying photograph.

The capacity of this crane truck is just less than that of the smaller industrial steam or gas operated locomotive cranes. It has a lift capacity of 3,000 lb. at a 6-ft. radius and 1,000 lb. at a 12-ft. radius. It can stack loads to a height of 12 ft. when set to lift 3,000 lb. at 6 ft. radius. This work is accomplished without the use of outriggers.

The truck has been specially designed of a heavy construction which will give stability and stand the strains of lifting. The boom and hoist, being independent of the driving motor, may be operated while the truck is in motion. All the standard Elwell-Parker truck features are incorporated in the new design. This truck is claimed to be the largest capacity electric industrial crane truck manufactured.

NEW ELECTRIC CRANE TRUCK

Synopsis of Recent Chemical & Metallurgical Literature

Physico-Chemical Problems Relating to the Soil

The *Transactions* of the Faraday Society, vol. 27, part 2, reports a general discussion held on May 31, 1921. Following the introductory remarks of Prof. A. W. Porter and Sir A. D. Hall, are two papers by E. J. Russell and G. W. Robinson. Then come five papers on "Soil Moisture" by B. A. Keen, Prof. Sven Odén, C. A. Shull, Prof. D. R. Hoagland, and F. E. Haskett; three papers on "Organic Constituents of the Soil," by H. J. Page, S. Odén, and E. J. Salisbury; three papers on "Absorption Phenomena," by E. A. Fisher, E. M. Crowther, and C. G. T. Morison; and three papers on "Colloidal Phenomena," by S. Odén, N. M. Comber, and J. W. Mellor. A General Discussion of Capillarity comes next, with papers by Allan Ferguson, P. E. Dowson, and by F. C. Thompson.

The discussion of all these papers is particularly trenchant and admirable. We are too prone to accept without question the experiments, formulas, and conclusions of others, especially of those who have big reputations. It is only by continually questioning our own work as well as the work of others, all in a friendly and impersonal spirit, that we get a more perfect view of the total truth. It is surprising how new unsuspected factors will appear and modify our views and conclusions.

The papers bring out the three-cornered struggle for water between soil, plant, and atmosphere. If the plant transpires moisture more rapidly than the soil will give it up, the plant wilts. At the wilting coefficient, the soil withholds water from the plant with a force of about 4 atmospheres and there is always some water held by the soil despite the osmotic pull of the plant which usually runs over 7 atmospheres. A wheat crop usually transpires about 1,000 tons of water per acre. But the water moving to the roots must bring with it the necessary plant food, or the plant will not thrive. In none of the various papers is consideration given to the "capillary phenomenon" of Bechhold, about which there has recently been some discussion in *Science* between the reviewer and Dr. Frierson. Soluble salts in plaster of Paris, soil and similar capillary bodies, move toward the surfaces where evaporation occurs, and this seems to account in part for the fact that cultivation (tillage) helps plants in dry weather. For even though some soil water be lost by increased surface evaporation from the soil immediately adjoining the plant, the recent work of H. A. Noyes (*J. Ind. Eng. Chem.*, Feb., 1922) indicates that the plant actually transpires less water when the water is richer in food. The soil near the roots is enriched by the capillary rise of salts due to increased local evaporation, which curiously thus conserves the total soil moisture. Cultivation therefore allows moisture to accumulate in the soil when rain is plentiful. Furthermore, it tends to increase the speed at which water reaches the neighborhood of the roots, and thus wards off wilting.

The work of Bouyoucos on the condition of water in the soil should be of interest to those who think that all attraction of this kind is "chemical," especially since F. W. Parker recently showed (*J. Am. Chem. Soc.*, 1921, p. 1011) that finely divided insoluble substances depress the freezing point of water, benzene and nitrobenzene and concludes that "the force holding water or other liquid films on solid particles and causing a freezing-point depression is adhesion."

When humus exercises a deflocculating action, as in the presence of soda or similar alkali, the effect on the soil is bad, for the colloidal matter washes down and may aid in forming a pan. Lime (usually present) forms "calcium humate" which is insoluble and aids in giving soil the desirable tilth, or fine granular state best suited to plant growth.

The papers show that the prevailing view is that the soil is a mineral framework surrounded by a jelly-like layer. But there is conflict between the "chemical" and "absorption" theories of the breaking up of salts in soils. Dr. W. R. Ormandy in discussing Prof. Odén's view that the "breaking up by adsorption is highly doubtful," reported experiments made with pure china clay (aluminum silicate) chosen to minimize the number of variables. In estimating by electric conductivity the amount of alkali in excess of what the clay would adsorb (about 0.2 per cent), the usual type of curve was obtained when the voltage was under 1.68 volts. Above this the adsorbed alkali was set free, increasing the conductivity; but it is at once readsorbed. Is the caustic soda chemically combined with the clay? "We have found that clay which has adsorbed the maximum amount of caustic soda to leave a neutral solution behind it will not adsorb copper, nickel, or other salts, but that such clay not treated with caustic soda does adsorb metallic salts. Similarly clay which is saturated with caustic soda will adsorb quite a lot of phenolphthalein without, however, becoming in any way colored. If distilled water have clay suspended in it, and the mixture be titrated with caustic soda, alkali will be adsorbed and it will appear as though it were an acid, but if the alkali be estimated electrically, such adsorption will not be found if a voltage of over 1.68 be employed."

It will be interesting to see how these observations of Dr. Ormandy will influence our judgment as to what happens when proteins are brought to the isoelectric point, or their hydrogen ion concentrations are determined. The adsorptive action of soils is so powerful, that as Mr. Veen remarks in his paper, "It is quite an easy matter to remove liquid from soil, of course, but it is another matter to say whether the liquid so removed is a true sample of the soil solution as it exists *in situ*." Considerations like this are interesting in connection with experiments recently reported by Dr. J. Loeb wherein he decanted from swollen gelatine particles the supernatant fluid and then determined separately the hydrogen ion concentration of the gelatine and of the decanted fluid. It is a question as to how acid or alkali are fixed, not only by proteins but also by many other "amphoteric" substances, like clay. E. A. Fisher advocates the use of the term "sorption" as suggested by McBain, "a word which emphasizes our ignorance of the nature of many of these reactions and which does not commit us to any particular theory."

JEROME ALEXANDER.

Book Reviews

A MANUAL OF FLOTATION PROCESSES. By Arthur F. Taggart New York: John Wiley & Sons. 181 pages. Price $3.

The evident intention of the author has been to write a book for purposes of instruction in ore-dressing classes or for other students of flotation. From this standpoint the book is remarkably well written. It is divided into four chapters, consisting of an introduction, a chapter on laboratory testing equipment, a chapter on testing and a chapter on mill data. One other avowed purpose of the book is stated in the preface, "to counteract the further spread of false conceptions concerning flotation concentration, by setting forth some of the essential facts which contradict them." This statement immediately follows a condemnation of Minerals Separation for its policy of opposition to the spread of knowledge of the process and "their unfounded claims that all processes prior to that described in U. S. Patent 835,120 were laboratory curiosities or commercial failures and that those subsequently discovered were merely improvements of that process." Evidently with this in view, a very clear exposition of the different methods of flotation is given the division being made into skin flotation, (bulk) oil flotation and froth flotation. The author further subdivides froth flotation into pulp-body concentration processes and bubble-column processes. He claims that the concentration of flotative mineral particles onto bubble surfaces takes place in the body of the pulp in processes like the old style agitation Minerals Separation process, whereas in pneumatic machines of the Callow type, where a deep column of evanescent bubbles is formed the selection of flotative minerals takes place in the bubble column and the gangue drops out of it. The two chapters on laboratory testing machines and on testing are very well written and should be adapted to class instruction. The chapter on mill data contain

drawings of different types of commercial machines, typical flow sheets, formula for calculations involved in mill control and a few conversion tables. This book should fill the need for a laboratory manual suitable to college classes. A more extensive treatise on flotation is to follow in another volume.

OLIVER C. RALSTON.

WITHIN THE ATOM, a popular view of electrons and quanta. By *John Mills*. 215 pp., 5x7½ in. New York. D. Van Nostrand Co. 1921. Price $2.

As the name indicates, this little book is a Cook's tour through the new physics. Not the physics which we were taught in high school and college—the physics which had to do with matter in the aggregate, chunks of matter which you could weigh, energy waves which you could see, hear or feel, or electrical currents which you could measure—but the physics which has to do with matter (or is it energy?) in the ultimate, a subject which our ancestors might even call metaphysics.

At times the author appears in the pitiable plight of the Senator who is both for and against the bonus. He must talk to an audience which presumably knows no science, yet tell it of the speculations of the most scientific. So he explains the meaning of such terms as "component" and "absolute zero," and on the next page says "Ionizing impacts in a conducting gas usually remove a single electron from such stable structures as the inert atoms." On the horns of such a dilemma Mr. Mills stages about midway in the book a vaudeville stunt wherein Proton, Electron, Voice of Energy, Author and Reader—both scientific and general—crack jokes and jazz things up generally. This was so fatiguing that the remaining chapters were negotiated with difficulty.

On the whole, the book is an excellent illustration of the fact that its reaction on the reader depends a great deal upon his understanding of the subject. Chapters on the periodic table, radioactive disintegrations, X-rays and atomic numbers are clear and excellently written. On the other hand, equally skillful chapters on Isolating a Proton and Quantum of Energy are much harder reading—that is, to the present reviewer. Another whose general stock of information is more physical than chemical would doubtless reach exactly the opposite conclusion. In other words, if you already know something of the matter, the book will be interesting—if you don't, it will be pretty dry.

Well-informed people—be they engineers or just "folks"—will want to know something about the recently acquired information on the constitution of matter. Most of them will have to depend upon such books as this, and there is no reason why they should not start in on Mr. Mills' little book. But please don't let him get you worked over the fact that energy is no longer thought to be transmitted continuously—that is, by infinitesimal amounts. No, it is not so; it is reasonably certain it is discharged, in chunks, quanta, so called. A quantum may be as large as 5×10^{-12} erg; which of course is quite sizable to an active imagination!

E. E. THUM.

A COMPREHENSIVE TREATISE ON INORGANIC AND THEORETICAL CHEMISTY. By *J. W. Mellor*, D.Sc. London and New York. Longmans, Green & Co., 1922. $20 net per volume. Volumes I and II.

The reader will find this review a distinctly prejudiced one. Some years ago we studied a book by Dr. J. W. Mellor called "Modern Inorganic Chemistry." In fact, we nearly memorized it. All the facts in inorganic chemistry which were not in that text, hung upon the outline presented in the book much as one hangs crystal balls and ornaments on a Christmas tree. Well, anyway, we passed the examination and that book has thus become associated with successful conquest. We love it and when we turn to review its big brothers we realize that we are inevitably prejudiced in their favor.

It can safely be said upon the evidence of the first two volumes that this monumentally conceived work is based upon the shorter text, "Modern Inorganic Chemistry." It gives the same perspective, the same development of the subject and to a large extent the same order of treatment, although it is of course expanded so that it gives the whole story and not a part of it. In general, the treatment of any subject is historical with the high points of fundamental research all mentioned together with original references thereto. The chronological development of each subject is stressed and numerous references within the last two years are evidence that the work is up to date.

We were amazed and altogether pleased to find that the text is readable. We had rather expected to find it simply a compilation of data, a somewhat elaborated Landolt-Boernstein. It is not that kind of a book at all. It is correctly named "a treatise," for it developes chemical theory according to a definite plan, much as a text book would.

It can hardly be considered a text book except for advanced students who will find it invaluable. As a reference book for studying the development of any subject in inorganic chemistry it is accurate and complete. It will undoubtedly have its greatest use in that capacity although we commend it most heartily to serious students of inorganic chemistry who desire to obtain a comprehensive idea of the subject.

Volume I contains a complete discussion of chemical theory developed systematically and as far as any given point is concerned chronologically. As mentioned above it follows the general plan of "Modern Inorganic Chemistry," and this presentation is excellent. We do not think it would be as good for elementary work as, for example, MacPherson and Henderson, but it is by no stretch of the imagination an elementary text book. Volume I also contains a discussion of hydrogen and oxygen and their properties at a point convenient to the better presentation of the gas laws. Volume II contains the halogens and the alkali metals.

The typography is good. The references to literature are all grouped at the end of each section and there are many points which commend this practice although in some ways it is not so convenient as including them as footnotes. The references are in excellent type, the names of the authors and the source being printed in different type as well as the volume numbers and date and page numbers. This makes it exceedingly easy to pick out references. In the text itself in discussing elements or compounds, the physical properties are printed in heavy type, that is to say, a sentence will begin, "The **density** of calcium chloride." This procedure is excellent and makes it extremely easy to locate the physical property in which one is particularly interested and to obtain data quickly and easily. So also in historical discussions, important words are printed in heavy type. In this respect the book is about as nearly perfect as any with which we have come into contact.

The dedication is interesting—"To the privates in the great army of workers in chemistry. Their names have been forgotten; their work remains." Of course the price of the book is rather prohibitive for the individual "private in the great army of workers in chemistry" and so its distribution will be largely in libraries of corporations, universities and technical societies, but its usefulness is great. Professor Mellor has rendered a great service and rendering that service will be his greatest reward unless it be the largely unvoiced thanks of the privates for whom he writes.

CHARLES WADSWORTH.

HENDRICKS' COMMERCIAL REGISTER OF THE UNITED STATES FOR BUYERS AND SELLERS. Thirtieth annual edition for 1922. 2,324 pp. New York: S. E. Hendricks Co., Inc. Price, $15.

No more convincing proof of the fact that chemistry is an inseparable part of industry can be found than by a study of some comprehensive trade directory such as this new edition of Hendricks'. The products of the chemical and chemically controlled industries enter into practically every ramification of the manufacturing field. To be acquainted thoroughly with all these products as well as the raw materials from which they are derived is obviously beyond the ken of even the technically trained purchasing agent or sales manager. These are the men, however, for whom this book can render yeoman's service. Manufacturers and producers of chemicals and

cognate materials, chemical apparatus, equipment, machinery, containers—in fact, every requirement of the chemical industries—are adequately covered under a suitable heading and are conveniently cross-indexed under a half dozen others. Next comes the lists of hundreds of jobbers and dealers specializing in the sale of chemicals and chemical supplies. And last, but perhaps of most importance, are the consumers—from the smallest chemical laboratory to the largest industrial plant. Thus the picture of industry is complete, for we have production, distribution and consumption, from the crudest raw material to the most intricately fabricated finished product.

The outstanding improvement in the new edition is the change in the type page to the generally accepted standard size. In its new size the larger page (8½x11¼ in.) naturally carries more printed matter and gives a thinner book, which in turn is easier to handle. According to the publisher's statement in the front of the book the increased size of the page would normally reduce the number of pages from 2,800 to 2,100, but enough new material has been added to bring the total up to more than 2,300 pages. As in earlier volumes, the various sections of the book are prominently set apart by different coloring of the front edges of the pages. The first section (blue) is an index to trade classifications and in it every product listed in the book is indexed and cross-indexed for ready reference. This is followed by the classified trade (red) covering 17,145 different classifications. The third section (white) is an alphabetical list of about 20,000 trade names, private brands, etc., together with the name and address of the manufacturer. From personal experience and without hesitancy the present reviewer is willing to testify to the daily usefulness of this very important section. The volume is completed with an alphabetical list of all firms whose products are listed in the book, together with their addresses and principal business.

S. D. KIRKPATRICK.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Potash From Silicates—This specification relates to the treatment of silicates, such as potassium-bearing silicates and clays, in order to recover their constituents in commercially available form. The silicate is fused with boron trioxide, or any substance that yields boron trioxide at a high temperature and the resulting melt suspended in water and treated with sulphur dioxide. Bisulphites of the metals present pass into solution, while silica remains undissolved and is filtered. The filtrate is boiled, whereupon sulphur dioxide is evolved, the bisulphites converted to sulphites, and aluminum precipitated as hydroxide. The precipitate is filtered and the filtrate boiled, in the presence of air, to oxidize sulphites to sulphates. At the same time any iron present is precipitated and filtered. The filtrate then contains sulphates of the alkali metals, if present, and boric acid. The constituents are separated by fractional crystallization, and the boric acid used again. (Br. Pat. 177,736. E. Levitt, Montreal. May 24, 1922.)

Bleaching Earths—The activity of bleaching earths comprising aluminum hydrosilicates, such as fullers earth and floridin earth is increased by treating them in the cold with dilute acid, such as hydrochloric or sulphuric acid of 1 per cent strength. The earth is afterwards filtered, washed with water, and dried. Known processes comprising cautious heating to expel hygroscopic water, or boiling for 2 hours with hydrochloric or sulphuric acid of 15 per cent strength to produce for example "Tonsil" or "Franconite" are referred to. (Br. Pat. 176,353. Not yet accepted. Schweizerische Sodafabrik, Zurzach. April 26, 1922.)

Hyposulphites — Hyposulphites are produced by reducing bisulphites by means of an amalgam such as sodium amalgam in the presence of an acid such as sulphurous, sulphuric, or hydrochloric acid. The quantity of acid added is preferably equivalent to the metal dissolved in the mercury. The amalgam may be produced electrolytically and led by a siphon to a closed vessel containing the bisulphite solution, the mercury being returned to the electrolytic cell. (Br. Pat. 176,344. Not yet accepted. Bayer & Co. Leverkusen. April 26, 1922.)

Metaldehyde — The stability under heat of metaldehyde prepared by the catalytic polymerization of acetaldehyde is improved by transforming the residual traces of catalyst into substances devoid of catalytic action or by eliminating any adhering paraldehyde. Thus, if sulphuric or hydrochloric acid has been employed as catalyst, a barium or silver compound respectively may be added; adhering paraldehyde may be removed by washing with acetaldehyde or by gently heating in *vacuo*. (Br. Pat. 176,319. Not yet accepted. Elektrizitätswerk Lonza, Basle. April 26, 1922.)

High Explosives—Crystalline compounds of the mixed crystals and double salts type containing the potassium salt of dinitrodinitrosobenzene and difficulty soluble salts of azoimide, tetrazol derivatives, or mono- or poly-nitrated phenols, for example lead azide, azotetrazol and tetrazylazoimide salts, trinitroresorcinates, and trinitrophloroglucinates, are employed for loading ammunition generally and as a top charge in detonators. (Br. Pat. 177,744. H. Rathsburg, Fürth, Bavaria. May 24, 1922.)

Activated Carbon—Consists in subjecting wood charcoal to a partia vacuum, impregnating with alkali caustic or carbonate, heating to a high temperature such as a bright red hea and extracting the alkali. In an ex ample, 200 parts of wood charcoal ar subjected for half an hour at 20 deg C. to a vacuum of 720 mm. of mercury and then impregnated with a solution of 250 parts of potassium carbonate i 250 parts of water. (Br. Pat. 179,108 W. Carpmael, London. June 21, 1922.)

Formaldehyde—Formaldehyde is ob tained by passing a mixture of ace taldehyde and oxygen, air or othe oxygen-containing gas over a heate catalyst, especially a metal or a meta oxide; suitable catalysts are copper silver, or other metals forming easily reducible oxides, and also oxides o metals forming several oxides, for in stance, vanadic and cerium oxides steam or indifferent gases may be pres ent. According to an example, ai containing acetaldehyde is led over coil of copper wire netting and the into water. Unchanging acetaldehyd is separated by fractional distillatio from the solution of formaldehyde ob tained. (Br. Pat. 178,842. Not ye accepted. Consortium fur Elektro chemische-Industrie Ges., Munich. Jun 21, 1922.)

Borneol and Camphor—Borneol i obtained by treating pinene hydro chloride with a hydroxide, such a calcium hydroxide, or with boilin water.

Camphor is produced from pinen hydrochloride by simultaneous treat ment with an oxidizing agent and "dehydrogenizing" substance. Metall oxides and peroxides, such as iro oxide and lead peroxide, are given a examples of oxidizing agents; bisu phates, such as potassium bisulphat and bicarbonates are mentioned a "dehydrogenizing" substances. Cam phor may also be produced by treatin borneol with a peroxide or the lik (Br. Pat. 178,797. Not yet accepte A. Gawalowski, Brünn, Czecho-Slovak and L. Kutter, Vienna. June 21, 1922

Plastic Composition—A plastic com position for covering walls, floor and other surfaces and for makin moulded articles consists of 33 lb. magnesite rendered caustic, 11 lb. wood-meal, and 5 lb. of limestone me mixed into a stiff paste with a 20 p cent solution of magnesium chlorid 2½ lb. of talc and 2½ lb. of colourin matter may be added to the ingredient An imitation marble is produced rubbing the paste through a 1 c sieve to produce granules, mixing d ferently-coloured granules together a subjecting to pressure. When used f covering floors, tables, etc., the co position is applied to a backing consi ing of a wooden framework interstic of which are filled with a mixture wood-meal, magnesite, and magnesiu chloride solution. (Br. Pat. 178,880. Chesterton, St. Margarets-on-Tham June 21, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Grand Jury Investigates Chemical Foundation

Manufacturers Express Confidence in Administration of Foundation and Point Out Baleful Effect in Administration of Foundation ment of Justice Interprets Government's Action

THE Grand Jury investigation of the Chemical Foundation is under ay. Mr. Garvan and the books of the oundation are in Washington. Im-ortant developments were lacking dur-g the past week. The demand of the resident, the charges of German influ-ıce by Mr. Garvan and the instigation criminal proceedings against the oundation followed each other like many bombshells. Now, apparently, ıe fireworks are over for the present. the meantime, however, the industry a whole, having recovered somewhat om the shock, is beginning to figure ıt the ultimate results of the whole fair.

Formal Refusal by Garvan

As previously announced by Mr. Gar-ın, the Chemical Foundation has no tention of complying with the Presi-nt's demand. In a letter transmitted Alien Property Custodian Miller, Mr. ırvan officially proclaimed this stand. ıe text of the letter follows:

Hon. Thomas W. Miller.

Dear Sir:—This will acknowledge the receipt of your communication dated July 6, 1922, demanding that this company return and deliver to you all patents, trade-marks and copyrights heretofore assigned to this company by the Alien Property Custodian, that the company account to you for all income received by it from such patents, trade-marks and copyrights, and that the company forthwith cease to exercise any dominion over such trade-marks, copyrights and patents.

In reply thereto you are advised that this company is the owner, in its own right, of all the aforesaid patents, trademarks and copyrights and of the income derived therefrom. The company denies that the United States Government, or you, as Alien Property Custodian, or any one other than this company has any right, title or interest in said patents, trade-marks and copyrights. The company, therefore, declines to comply with your demand in any particular whatsoever.

The communication was signed by r. Garvan as president of the Founda-n and William D. Guthrie as counsel. The Foundation president also sent long letter to the Chief Executive ex-aining his position and that of his mpany. The letter, which is dated ly 14, says that "the American pub-, in whose interests this corporation as organized, is entitled to be fully informed as to the circumstances under which this demand was made and the reason why it is unqualifiedly refused."

"The Alien Property Custodian," continues the letter, "stated no authority or reason for his demand for the entire property and assets of this corporation for an accounting of all its past business and for the entire cessation of its activities, except that he was acting by your express direction. I am therefore compelled to imply that he was acting under the letter given out by you and the statement of the Attorney General accompanying it.

"These two papers demonstrate that you, Mr. President, have been grossly misled by the Attorney General, both as to the law and the facts of this case."

Mr. Garvan then quotes at length from a report of A. Mitchell Palmer dated Feb. 22, 1919, in which Mr. Palmer announced the sale of 4,500 patents for $250,000 and announced that the new company would be able "to commence immediately and prosecute with the utmost vigor infringement proceedings whenever the first German attempt shall hereafter be made to import into this country." In the Palmer report he referred to Mr. Garvan, the first president of the Chemical Foundation, saying of him " * * * to whose vision and indefatigable industry I am chiefly indebted in the working out of this plan."

Mr. Garvan's letter to the President continues:

"Note that at the time this was written I was a dollar-a-year man, with no expectation of becoming Alien Property Custodian, and at a time when I thought my own war services were over and I was about to return to New York to resume my law practice."

The letter includes a summary of the finances and activities of the Foundation.

Manufacturers Back Foundation

"Nothing could be more disastrous to the American industry than the return to the former German owners of the patents now owned by the Chemical Foundation; nothing could be of greater aid in restoring to the German chemical cartel the monopoly formerly enjoyed." Such is the statement in a memorandum submitted to the President at a conference at the White House by a delegation of representative manufacturers of dyes, medicines and other synthetic organic chemicals.

The committee which conferred with the President included Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers' Association of the United States; C. N. Turner, Newport Chemical Works, Passaic, N. J.; Alfred S. Burdick, The Abbott Laboratories, Chicago, Ill.; W. T. Cashman, Grasselli Chemical Company, Cleveland, Ohio; Samuel Isermann, Chemical Company of America, New York City; Charles A. Meade, E. I. duPont deNemours & Co., Wilmington, Del.; August Merz, Heller & Merz, Newark, N. J.; James T. Pardee, Dow Chemical Co., Midland, Michigan; Fred E. Signer, Butterworth-Judson Corporation, New York City; Herman Seydel, Seydel Manufacturing Co., Jersey City, N. J.; Franklin P. Summers, Noil Chemical & Color Co., New York; Salmon W. Wilder, Merrimac Chemical Co., Boston, Mass.; Edgar F. Queeny, Monsanto Chemical Works, St. Louis, Mo.; George A. MacIntosh, Butterworth-Judson Corp., New York, and Edward S. Rogers, The Bayer Company, New York City.

The statement points out that prior to the war there was practically no organic chemical industry in the United States; this was almost wholly controlled by the Germans and commodities necessary to the safety of the nation and the health and prosperity of the people were solely in their hands. The Germans took out many thousands of patents in the United States. They never exploited them. The sole purpose in holding these patents was to prevent the American manufacturer from building up an organic chemical industry.

The statement submitted by the manufacturers included a review of the circumstances leading up to the organization of the Chemical Foundation and the sale of the siezed property to it by the Alien Property Custodian. It was pointed out that the main consideration in the transaction was the assurance that these patents were to be held in trust for the benefit of the American people by the Foundation. They are non-exclusive in character and license to operate under them is open to every American citizen.

The American manufacturers who have taken out licenses had implicit faith in the authority of the United States Government to make the sale to the Chemical Foundation. Relying upon this authority and believing that the Government desired to foster and encourage an industry vital to the

needs of the country they have invested over $100,000,000, and this will be entirely lost to them, and the loss to the country irreparable if these patents are restored to the Germans.

The attitude of the organic chemical manufacturers toward the administration of the Chemical Foundation is evidenced by the resolution passed by the Board of Governors of the Synthetic Organic Chemical Manufacturers' Association at the meeting held on July 11, 1922, which "expresses (1) its appreciation of the patriotism and forethought of those representatives of government and industry who conceived this plan; (2) its entire confidence in the administration of the affairs of the Chemical Foundation; (3) and records its appreciation of the personal sacrifices of the Foundation's president, Mr. Francis P. Garvan, who, at the solicitation of the founders of the organic chemical industry in the United States, accepted the presidency of the Foundation at its inception and since that time, without remuneration, has administered disinterestedly its affairs in behalf of the welfare of the people of the United States."

Department of Justice Statement

The Department of Justice has issued a statement relative to the government's purpose in proceeding against the Chemical Foundation. Officials of the department say that representatives of the German cartel, comprising the organic chemical industry of Germany, called at the Department of Justice recently relative to thirty-odd suits to be instituted by them against the government on behalf of their clients, but that they had absolutely nothing to do with any action of the department against the Chemical Foundation. It was pointed out that the Department of Justice had been investigating the transaction between the Alien Property Custodian and the Chemical Foundation for many months prior to the arrival of the German representatives, as Mr. Garvan and his associates well knew, and prior to the action of the Chemical Foundation in precipitating an unexpected situation by bringing sixty-seven suits against the government, involving a very large sum of money.

It is pointed out that the return of these patents to the Alien Property Custodian would in no sense benefit the former German owners or interests. The action taken by the government has been wholly in the interest of the government itself. The disposition of these patents after return to the Alien Property Custodian, as well as all enemy property held by him, must be determined by action of Congress.

Civil Service Openings Announced

The U. S. Civil Service Commission has announced an open examination for a microscopist to fill a vacancy in the Public Health Service in Memphis, Tenn. Applications should be made on form 1312 to the Civil Service Commission

Preliminary Program Announced for Fall Meetin of American Chemical Society

Two Thousand Members Expected at Pittsburgh Convention in September—Strong Technical Sessions Scheduled but Entertainment Features Not Neglected

THE preliminary program for the Pittsburgh meeting of the American Chemical Society, which will be mailed to members the latter part of this week, gives promise of a splendid success. All of the regular divisions of the society and the five sections are planning extensive programs. The central location of Pittsburgh augurs well for the attendance and officers of the society estimate the probable attendance at 2,000. With the Chemical Exposition in New York the following week and the American Electrochemical Society meeting in Montreal after that, the month of September should be an outstanding one in the chemical field.

Bargain Railroad Rates

The peculiar satisfaction that everyone experiences in getting a free ride on a "common carrier" will be the lot of each member who makes the trip to Pittsburgh, in some degree, at least. In view of the expected large attendance the railroads have agreed to sell round trip tickets at one and one-half fare on the certificate plan, the intricacies of which are too well known to be described here. Nevertheless, it will make a much more presentable expense account for members coming from a distance and those who were disappointed in the failure of the required number to register at Birmingham last spring will be pleased to know that this economy is assured.

The official registration at the meeting will begin Monday afternoon, Sept. 4. Pittsburgh's well known hostelry, the William Penn Hotel, will be headquarters for the registration and for the council meeting, which is scheduled for the same evening. The Duquesne Club has thrown open its doors to the councillors, who with their wives will be entertained there at dinner, Monday evening, after which theatre parties have been arranged for the ladies.

General Meetings

The first general meeting will be held at Carnegie Music Hall on Tuesday morning. Prominent local officials will extend greetings and welcome to the visiting members and Edgar F. Smith, president of the Society, will respond—a prospect that will appeal to anyone who has had the pleasure of hearing Dr. Smith on similar occasions. Included in the formal addresses at this session will be two dealing with Pittsburgh as an industrial center. J. H. James will describe the historical and industrial features of the city and W. F. Rittman will discuss the phases of finance and transportation.

The second general meeting, the same afternoon, offers a program that could be equalled only with difficulty as fa as the variety and current interest the topics scheduled are concerne No research conducted in the past ye has stimulated more general intere or appealed more to the practical si of technologists than has the extensiv work of the General Motors Corpor tion on motor fuel and anti-kno compounds. Thomas Midgeley, Jr. a T. A. Boyd, both of whom have be directly connected with these invest gations, are to present a paper "The Chemical Control of Gaseo Detonation with Particular Referen to the Internal Combustion Engine The talk will be illustrated with slid and with the ingenious apparatus us in the experimental work.

E. J. Crane, editor of *Chemic Abstracts*, will present a paper "The Journal Literature of Chemistry

Wilder D. Bancroft is scheduled f a discussion of his novel conception "Structural Colors in Feathers." Tho who have been fortunate enough hear Dr. Bancroft's talk on "Bl Eyes and Blue Feathers," at vario sectional meetings will appreciate opportunity to listen to a further e position of this fascinating topic in t inimitable manner of Cornell's di tinguished exponent of colloidal che istry.

Divisional Meetings

As stated above, the twelve divisio of the Society are arranging extensi programs for Wednesday and Thu day. In addition, the technical sessio will be augmented by the convening five sections, including the new formed section of gas and fuel che istry. All these sessions will be h at Carnegie Institute of Technolo Of special interest to the engineer v be the symposium before the Divis of Industrial and Engineering Che istry on "Automatic Process Contr The chairman, L. W. Parsons, has ranged with various authorities to p sent papers, many of them illustrat bearing on the fundamental and pr tical aspects of the subject.

The Water, Sewage and Sanitat Division will discuss the specificati for lime for water treatment as feature of the meeting. Under chairmanship of David Wesson, Biological and the Agricultural Food Chemistry Divisions will hol joint symposium on the subject "Fatty Foods." In view of the re developments in the study of vitam at Johns Hopkins, this meeting sh prove of timely interest. Papers d ing with the preparation, purificat digestibility and adulteration of var fatty foods are being solicited for symposium.

The Rubber Division is planning an exceptionally live program, as the proximity of Pittsburgh to the center of the rubber industry will facilitate the attendance of representatives of the industry. The Leather Division has scheduled a symposium on gelatine and collagen. An important phase of the dye industry and one which has not previously received a proportionate share of attention, will be discussed by the Dye Division—"The Chemistry of the Application of Dyes." The Division of Physical and Inorganic Chemistry will hold a symposium on "Recent Advances in Applied Colloid Chemistry."

The Petroleum Section hopes to perfect its divisional organization at this meeting as provided by the Council at Birmingham last spring. The feature of the technical sessions will be a discussion of "Lubrication from the Chemist's Viewpoint." As previously announced in these columns, the newly-formed Gas and Fuel Section has arranged a symposium on "Combustion" under the chairmanship of R. T. Haslam, of Massachusetts Institute of Technology. The Cellulose Section has a number of papers on live topics on its projected program including "Co-operative Research Problems in Cellulose Chemistry," "The Nature of Oxycellulose and its Bearing on the Artificial Silk, Viscose and Paper Industries," "Dr. Tingle's Proposed Bromine Number" and "The Absorption of Salts by Cellulose." The Sections of Chemical Education and the History of Chemistry will be watched with more than usual interest in view of recent educational developments.

Social Activities

The usual smoker, with unusual features (as yet obscure in the carboniferous atmosphere of the Smoky City) is planned for Tuesday evening at the commodious Syria Mosque. Being strictly a "stag party" the ladies will be entertained that evening at Carnegie Institute of Technology, where the Drama School has arranged to present a play for their special benefit.

Nor will the fair guests be given opportunity for thumb-twiddling during the divisional meetings for they are to be the guests of the Heinz factory on an inspection trip and at luncheon which will include the majority of the 57 varieties. In the afternoon a musicale at the Century Club has been arranged for their entertainment.

The public meeting, Wednesday evening, at Carnegie Music Hall will be followed by a reception. On Thursday evening, the University of Pittsburgh Faculty Club has arranged for supper and garden party.

Trips

The trips to nearby industrial establishments which are scheduled for Friday and Saturday will include visits to the famous steel mills in the vicinity and numerous other chemical industries which cluster about this city of industrial activity.

All Muscle Shoals Offers Rejected

Committee on Agriculture Turns Down Ford Offer with Others—Minority Reports To Be Submitted

All of the offers for the Muscle Shoals nitrate plants and power site were summarily disposed of by the Senate Committee on Agriculture on June 15, when that body rejected Henry Ford's offer by a vote of 9 to 7. The Alabama Power Co., the Engstrum and the Parsons offer were turned down without the necessity for a roll call. Senator Norris' proposal for the government operation of the plants met a similar fate.

Senator Ladd, who voted for acceptance of the Ford offer, was authorized to draw up the minority report in favor of that proposition while Chairman Norris will write the report urging approval of the government-owned corporation plan. Both reports, it was said, will probably go to the Senate in the coming week, although it is not believed that any action on either of them will be taken at this session of Congress.

Fire in Subway Brings Chemistry Home to Public

Fumes Liberated by Carbon Tetrachloride Extinguishers Overcome Scores of Straphangers in New York

The recent fire in the New York subway, during which one hundred and fifty persons were overcome by the fumes evolved by the volatilization of carbon tetrachloride has given rise to considerable comment on the part of the public and the daily press. As is usual in incidents of this kind, the newspapers carried lurid descriptions of the "acrid fumes of carbon dioxide" and other novel and revolutionary conceptions of elementary chemistry.

Making due allowance for the natural effects of the excitement incident with such an occurrence, it is fairly well established that a number of the victims were actually affected to a certain extent by the gases evolved from the use of carbon tetrachloride fire extinguishers. Fortunately, no one was seriously disabled. The occurrence served to emphasize the danger of the unintelligent use of this very efficacious material. Work by the Bureau of Mines has demonstrated that the decomposition products of carbon tetrachloride consist of phosgene, hydrochloric acid gas and sometimes chlorine. In addition, high concentrations of tetrachloride vapor are formed when the liquid is sprayed on a heated material. Death may be caused by breathing the gases for only a short time. It is obvious that the danger of such an occurrence is considerably greater in a confined space where there is not opportunity for the diffusion of the noxious gases.

A report issued by the Bureau of Mines, written by A. C. Fieldner, S. H. Katz and S. P. Finney, contains the results of the work done by the Bureau on this subject. The following extract is offered as an authoritative statement on a subject which vitally concerns the public welfare.

> Seven to nine per cent of carbon tetrachloride vapor mixed with air will extinguish fires. The heavy vapor tends to settle to the bottom of a room and forms a blanket on the floor.
>
> This blanketing effect on any material wet with carbon tetrachloride excludes air and so aids in extinguishing fires.
>
> Undecomposed carbon tetrachloride vapor, arising from the use of the liquid in fire extinguishers when encountered in a small, confined space will probably produce unconsciousness by its anaesthetic effect. The commercial product usually contains some carbon bisulphide, a residue of the carbon bisulphide used in its manufacture. Waller and Veley have found that the presence of carbon bisulphide vapor with that of carbon tetrachloride greatly increased the toxicity, but comparatively large amounts of the carbon tetrachloride vapor must be breathed before the effects become more dangerous. For this reason the more serious danger in the use of carbon tetrachloride lies in the products formed from it rather than from the vapor itself.
>
> An employee of the Bureau of Mines was overcome while using a carbon-tetrachloride fire extinguisher on an automobile burning in the open air. Two employees of the Navy Department died as the result of breathing fumes from carbon-tetrachloride that had been used when the clothes of one of them caught fire when the men were working in a very small compartment.
>
> Care must therefore be observed in the use of fire extinguishers of the carbon-tetrachloride type in underground fire fighting. Such extinguishers are in common use for putting out fires in and around electrical equipment, for carbon-tetrachloride is a non-conductor of electricity, and, indeed, such extinguishers should be a part of the equipment of all mine locomotives. The operator need not inhale the fumes, as electric locomotives usually are in well-ventilated entries or haulageways.

Steps have been taken to prevent a re-occurrence of such an accident by the removal of this type of extinguisher from subway cars in New York.

Sulphuric Acid Plant Built in India

The Dharamsi Moraji Chemical Co. has built a sulphuric acid plant of 7,500 tons per annum capacity. This is the largest plant of its kind in India. It is reported that the factory will also manufacture superphosphates and the results are being watched with the greatest interest. This factory is one of the first built in the new Ambernath area on the G.I.P. Railway which is being developed by the Bombay Protectorate.

Senate Votes Down Dye Embargo

Bolt of Republicans Kills Finance Committee's Recommendation—Sentiment of Legislators Believed Influenced by Chemical Foundation Trial

TO THE surprise of each party to the dye embargo controversy, the Senate, on July 15, voted down the proposal of the Committee on Finance to continue in force for one year after the passage of the tariff bill the embargo provided in the dye and chemical control act approved May 27, 1921. The vote was 32 for the embargo and 38 against. It is believed that the action of the administration in proceeding against the Chemical Foundation influenced a number of Republican senators to vote against the embargo. An informal poll of the Senate, less than a month ago, showed a margin of 3 votes in favor of the embargo.

While Senator McCumber, the chairman of the Finance Committee, made it very clear before the vote was taken that the embargo and the patent situations are entirely distinct, it is believed that fact was not brought home to certain senators who apparently made an eleventh-hour change in their attitude. The fight is not over. Senator Frelinghuysen gave notice that he will demand another vote on the proposal when the bill is considered in the Senate proper. This vote was taken in committee of the whole.

Herty Optimistic of Final Vote

Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers Association, characterized the action of the Senate as a severe blow to the American industry, but he believes the real test, whether America wishes to preserve its dye industry or turn it back into German hands, will come on the forthcoming vote. Continuing, Dr. Herty said:

"An analysis of the vote, to my keen regret, shows a solid Democratic vote against the embargo, in spite of the unanimous approval of this measure by consumers of dyes throughout the South. On the other hand, the division in the Republican vote, fourteen having voted against the embargo, shows clearly that there has been confusion of thought between two issues, patents and embargo, which logically have no connection in the consideration of this measure, as was so ably pointed out by Senator McCumber. I confidently believe that this confusion of thought will disappear and that when the measure comes before the Senate again it will receive that certain majority support which was so clearly evident before this question of patents arose."

The vote on the embargo paragraph was preceded by vitriolic attacks on the American dye industry by Senator Moses and by Senator King. Senator Moses said that if the embargo remains in the bill "we shall go before the country convicted of surrendering to an iniquitous, imprudent and avaricious monopoly." His attack on the American industry extends through 28 pages of the Congressional Record. Senator King's attack, which was largely a reiteration of his oft repeated charges, continued for nearly three hours.

Senator Shortridge, of California, told the Senate that after the extended and painstaking investigation which he conducted on behalf of the Senate, there was nothing disclosed to indicate that there is anything even approaching a monopoly in the domestic dye industry. In announcing his forthcoming report on the subject, Senator Shortridge addressed himself to Senator King and stated that, in making his conclusions, he would not rely upon rumor, and that he would not draw upon his imagination.

Sentiment in Favor of Embargo

The principal address presenting arguments in favor of the embargo was that of Senator Frelinghuysen, who took the floor at the end of Senator Moses' speech. He prefaced his remarks by stating that his speech had not been prepared for him by some one entirely familiar with these technical questions. The theme of his address is well set forth in the following brief extract:

"My fight for a dye embargo and my insistence upon its continuance is based upon two motives — first, to protect and continue the industry in my state and secondly, because I believe it is absolutely essential for the national defense, as I read the history of the war and what was accomplished by Germany by reason of her advanced position in chemical manufacture. This is a great question for the Senate to decide at this time. The only harm that will come from a dye embargo is to the German industries — the German cartel that furnished Germany with all her chemicals and ammunition during the war. If we make a mistake now and lift this embargo, it may destroy, and probably will destroy, this great industry, which was created during the war by the men of energy and genius who had the courage and the ability quickly to provide our armies with the necessary materials with which to meet the onslaught of Germany.

"There is just one question involved. Inasmuch as the former President of the United States, Mr. Wilson, recommended the embargo, since President Harding has recommended its continuance, and every Cabinet officer and military officer who is familiar with the situation and every man who has studied it makes similar recommendations, the question which we have to decide as to its continuance is whether we are going to stand for America first or for 'Deutschland uber Alles'."

Before the vote was taken, Senato McCumber made the following state ment:

"The only question before the Senat is the question of the embargo upo dyestuffs. On that subject there was disagreement in the committee itsel One thing we do know, that prior t 1914 a foreign nation, a foreign peopl furnished practically all the dyestuff for American manufacturers.

One thing we do know and that i that after we were engaged in the wa we found ourselves entirely cut off, o almost entirely cut off, from the dy products. We found, in addition, tha we had to pay many times the pre-wa value of our dye products. We the came to the conclusion that it wa necessary to develop the dye industr in the United States. The previous ad ministration inaugurated the idea o the use of the licensing system fo the development of the dye industry We followed along that pathway an along the previous idea of the Demo cratic administration and in our emer gency tariff law we provided for a embargo. How long the embargo shoul continue is, after all, a question to b determined by the Senate. We agree that it should be continued for anothe year. We know that as a rule, not withstanding the embargo, the price of dyes have gradually gone down fro the highest peak until now they ar only about 50 per cent of the hig prices of 1917.

It may be with the protection w have given them, the dye people will b able to continue to produce but, Mr President, I think in some instances the will not be enabled to continue the pro duction without the embargo for a brie length of time. That, after all, is th only question before the Senate toda not the trial of the Chemical Founda tion but the determination whether o not we desire to continue the dye in dustry in the United States an whether or not the duties that we in posed are sufficient, and if not su ficient for a space of one year, whethe we had better maintain the prese embargo. To that subject I wish v could direct our attention rather tha to be misled and drawn away fro the real question by a trial of a matt which is not before the Senate."

Society of Industrial Engineers To Meet in New York

The next national convention of t Society of Industrial Engineers will held in New York City, Oct. 18, 19 a 20 at the Hotel McAlpin. In conjur tion with the 3-day convention the will be an exhibition of labor-savi equipment. The business meetings w be held in the ball room of the ho and the exhibition in the Wint Garden.

The official program and the list speakers and their topics will not ready for distribution before the mid of September. The general topic discussion, however, will be "The E nomics of Industry."

Standard Oil Co. Called Monopoly but Proof Against Law

The Federal Trade Commission has sent to Congress a report on conditions in the petroleum trade in Wyoming and Montana. This report summarizes the important facts developed through an inquiry into the conditions of the petroleum trade in those states made pursuant to a complaint of the Montana State Railway Commission regarding gasoline prices.

The margins between the wholesale and retail gasoline prices at numerous points in Montana ranged from 5 to 10 cents per gallon, but these unusually large margins were in all cases obtained only by the smaller retailers. The wholesale and retail prices of the large marketing companies were usually identical at points taking the same freight rates and price changes were made by them at practically the same time. No evidence was found, however, which indicated a conspiracy among these large companies to fix prices.

Although the prices of high-grade crude petroleum were lower in Montana and Wyoming than in any other crude-producing states in the country, the refinery prices of gasoline and kerosene were much higher than at Mid-Continent refineries. The Midwest Refining Co. is owned by the Standard Oil Co. of Indiana and produces more than 90 per cent of the gasoline and kerosene refined in the entire Rocky Mountain territory. The Midwest Refining Co. also charges higher prices for gasoline shipped into Montana and adjoining Rocky Mountain states than for shipments made in states adjacent to the Mid-Continent oil field.

The unsatisfactory situation in Montana and adjacent Rocky Mountain states is evidently due to the fact that the oil trade in this region is practically monopolized by Standard Oil interests. This monopolistic position was perfected in 1920 and 1921, when the Standard Oil Co. of Indiana secured control of the Midwest Refining Co. and acquired a one-half interest in the Sinclair Pipe Line Co. and the Sinclair Crude Oil Purchasing Co. Sinclair interests have recently obtained important leases in the Teapot Dome of the Salt Creek field in Wyoming.

The conditions in other sections of the country are not radically different from those in the Rocky Mountain region. Today the entire country is divided into 11 Standard gasoline marketing territories in which a Standard marketing company is the dominating factor and in which there is no real competition between the various Standard units. This monopolistic situation is possible under the terms of the Standard Oil dissolution decree, by which the different Standard companies are, for legal purposes, supposed to be strangers to each other, but, there is, as is generally known, an interlocking stock ownership in the different organizations which has perpetuated the very monopolistic control which the Court sought to terminate.

The Commission is of the opinion that this situation cannot be effectually remedied by existing laws and that adequate relief can only be secured through additional legislation. It recommends, therefore, that Congress pass a law prohibiting common stock ownership in corporations which have been members of a combination dissolved under the Sherman law.

Electrochemists Organize to Stir Public Interest

On June 29 the local committee which so successfully handled the recent meeting of the American Electrochemical Society in Baltimore met for luncheon at the Hotel Emerson and decided to make the committee a permanent organization with the following objects:

1. To promote good fellowship among its members.
2. To arouse interest among the public at large in things electrochemical.
3. To act as an informal clearing house on electrochemistry with a view to attracting new electrochemical industries where possible to the Baltimore district.

W. H. Boynton, analytical chemist of the Crown Cork and Seal Co., was made permanent chairman. Other members are Ernest B. Miller, operating vice-president of the Davison Chemical Co.; F. M. Boyles, McCormick & Co.; Richard K. Meade, consulting chemical and industrial engineer of Richard K. Meade and Co.; A. E. Marshall, consulting engineer; C. C. Thomas, Williams and Wilkins Co.; W. C. Moore, research chemist of the U. S. Industrial Alcohol Co.; A. L. Browne, chemist; S. T. Powell; W. H. Stone, *Manufacturers' Record;* E. W. Rouse, assistant superintendent, Baltimore Copper Smelting and Rolling Co.; R. G. Gerhardt and R. H. Tillman, manager, new business department, Consolidated Gas, Electric Light and Power Co.

Citro Chemical Co. Wins Case

The Citro Chemical Co. has been upheld by the United States Court of Customs Appeal in its abandonment of a shipment of 168 casks of citrate of lime which had been damaged by sea water while en route from Messina. The law provides that notice of abandonment must be filed within ten days after the entry of merchandise. The invoice and the declaration were filed a month in advance of the arrival of the shipment. Since the declaration contains the perfunctory statement that the merchandise has arrived, it was contended that the chemical company could not have recourse to abandonment. The court holds however, that the actual date of entry must govern and since the notice was filed within ten days after the actual entry of the ship carrying the merchandise, the chemical company's contention must be sustained.

A.C.S. Alcohol Committee Secures Government Support

Martin H. Ittner, chief chemist of Colgate and Co., of New York, chairman of the Industrial Alcohol Committee of the American Chemical Society has announced that Wayne B. Wheeler of the Anti-Saloon League has assured him that the League will not attempt any new restrictions without first consulting the A. C. S. Alcohol Committee.

Dr. Ittner's Statement follows:

The Industrial Alcohol Committee believes in a literal interpretation of the 18th Amendment, also that no authority is conferred thereby to prohibit the manufacture, sale, transportation, importation, or exportation of intoxicating liquors for other than beverage purposes.

The main thing that the Committee on Industrial Alcohol is interested in and a thing that we are vitally interested in, is that there shall be no prohibition of alcohol either pure or in liquors where it is intended to be used for other than beverage purposes, i. e., for industrial and legitimate uses.

We recognize the necessity of laws and regulations to control these matters and we desire to see these laws and regulations as little burdensome as possible while accomplishing their proper purpose. We stand ready to give what aid we have, or can enlist, to the support of the Government in advising them with regard to laws or regulations that would prohibit or unduly restrict the proper use of alcohol.

Mr. Wayne B. Wheeler, counsel for the Anti-Saloon League, has assured me that they would not seek to pass any new laws or have any new restrictive regulations drawn up without first seeking our advice and that of representatives of the industries.

The trouble with the national prohibition act is in its improper enforcement. Title III which provides for the industrial use of alcohol, though equally as important as other portions of the law, has not been given the attention and recognition by enforcement officers that it should have had and to this extent industry has suffered.

The prohibition forces ought to see that every unnecessary restriction imposed on industry reacts through public opinion against them.

The statement also points out the undisputed right of Congress to regulate intoxicating liquors.

Progress in Investigation of Fluorspar Industry

The general investigation of fluorspar mining, milling and utilization problems is progressing rapidly through the field work of R. B. Ladoo, Bureau of Mines. Mr. Ladoo has completed field studies in the West and within a short time will have visited the eastern deposits of this mineral. It is planned to gather very complete information regarding methods of utilization of fluorspar and the specifications and requirements as to quality of this material.

Poison Gas Officially Tabooed by Army

War Department Orders Discontinuance of Manufacture Except for Research and Defense

The War Department's interpretation of the gas treaty adopted by the arms conference provides for the discontinuance of the manufacture of poison gas except in limited amounts for research and development of defense appliances. The definite announcement took the form of a general order signed by General Pershing as Chief of Staff, by direction of Secretary Weeks. The order follows:

> In order that the United States may carry out the provision contained in Article V of the treaty in relation to the use of submarines and noxious gases in warfare, signed, Feb. 6, 1922, and ratified by the United States Senate, March 28, 1922, the following limitations will be observed in connection with the procurement, design research, development and supply to cehmical warfare materials as given in Section III, General Orders No. 54, War Department, 1920.
>
> The investigation, development, procurement, manufacture, or supply of poisonous gases for the present will be limited strictly to the amount necessary for the research and development of gas-defense appliances.
>
> The filling of all projectiles and containers with poisonous gas will be discontinued, except for the limited number needed in perfecting gas-defense appliances.

MODIFICATIONS IN TRAINING

Another modification of existing regulations concerning the training of the army in chemical warfare was provided in another order confirming the use of smoke, incendiary materials and non-toxic gas for training and gas-defense appliances.

This order then directs that there shall be a special service school at which specified officers and non-commissioned officers of the army and the National Guard shall be trained. Provision is made for chemical warfare personnel as instructors in defensive chemical warfare at general service schools and at certain special service schools, and for representation on the staffs of departments, corps areas and divisions.

FUNDS AVAILABLE TO C. W. S.

The War Department appropriation bill which has been passed by Congress and approved by the President authorizes construction work at Edgewood Arsenal to cost $262,000. For administrative expense the Chemical Warfare Service is allowed $17,240 and $600,000 for investigations.

New Potash Fertilizer

A new potash fertilizer has recently been introduced in Sweden under the name "Electrokali." The material is the finely-ground slag from the electric-furnace manufacture of ferro-silicon from feldspar and iron turnings.

Salt Producers Association Restrained from Price Fixing

The Federal Trade Commission has issued an order to cease and desist against The Salt Producers Association, of Detroit, and the following members thereof: Michigan Salt Association, of Saginaw, Mich.; Michigan Salt Works, of Marine City, Mich.; International Salt Co. of New York, Scranton, Pa.; Worcester Salt Co., of New York City; The Colonial Salt Co., of Akron, Ohio; Morton Salt Co., of Chicago, Ill.; Ohio Salt Co., of Wadsworth, Ohio; Diamond Crystal Salt Co. of St. Clair, Mich.; Cutler Magner Co., of Duluth, Minn.; Union Salt Co., of Cleveland, Ohio; Stearnes Salt & Lumber Co., of Ludington, Mich.; Carey Salt Co. and Barton Salt Co., of Hutchinson, Kansas; and Mulkey Salt Co., Inland-Delray Salt Co., D. B. Doremus, all of Detroit, Mich.; Anthony Salt Co., of Anthony, Kansas.

The order prohibits the respondents from entering into any agreement or understanding among themselves to use any list of jobbers, wholesalers or other dealers in salt as a basis for allowance of jobbers' and wholesalers' prices and terms. The respondents are also ordered not to restrict, through concerted agreement, the number of purchasers who shall receive recognition as jobbers or wholesalers and not to refuse to sell, through agreement, to anyone not classified or listed as a jobber or wholesaler by any agency, publisher or person.

The complaint against The Buckley & Douglas Lumber Co., of Manistee, Mich., also a member of The Salt Producers Association, has been dismissed by the Commission upon its own motion.

Experiment with Silica Gel for Oil Refining

The Davison Chemical Co. has started operation of the experimental plant at Curtis Bay, Ind., for the study of silica gel in crude oil refining. The unit has a capacity of 40 barrels per day. The primary purpose of the installation is to study the cost of refining with silica gel. A number of oil companies have agreed to send carload shipments of oil for experiments. The present equipment at the plant provides only for the production of gasoline and kerosene but it is planned to extend the work to lubricating oils as the experiments progress.

Personal

E. F. BRUNDAGE, manager of the Baltimore branch office of the General Chemical Co. and superintendent of the plant, resigned to join the staff of Wing & Evans, Inc., agents for the Solvay Process Co. C. S. BENJAMIN has been appointed superintendent and acting manager at Baltimore, succeeding Mr. Brundage.

H. KENYON BURCH, who designed and built concentrating plants for the Inspiration Consolidated Copper Co., Miami Copper Co., Phelps, Dodge Corporation, and others, has opened offices at 806 Junion Orpheum Building, Los Angeles, Cal., and will design and construct a 5,000-ton concentrating plant for the New Cornelia Copper Co., at Ajo, Ariz.

E. L. DOHENY, chairman of the board of the Mexican Petroleum Co., has left New York for Los Angeles, Cal., where he will remain for a number of weeks.

V. L. HAVENS, editor of *Ingeniería Internacional*, expects to sail August 5, for South America, to attend the International Engineering Congress in Rio de Janeiro in September. He will probably visit also in Uruguay, Argentina and some other South American countries and will be gone for several months.

GEORGE B. HOGABOOM has resigned from the research department of the Scovill Manufacturing Co., Waterbury, Conn., to become a partner in Bennet & Seeley, Inc., Bridgeport, Conn., jobbers in foundry, electro-plating and finishing department supplies and equipment. Mr. Hogaboom expects to assist on electroplating engineering problems.

PAUL D. V. MANNING has severed his connection with the International Coal Products Corporation and has taken a position as chemical engineer with the Bregeat Corp. of America, 2 Rector Street, New York City.

T. B. PRESTON of Ionia, Mich., has been elected president of the Charles F. Noble Oil and Gas Co., Tulsa, Okla., succeeding Charles F. Noble.

H. B. PRIOR has been appointed New York representative for the G. T. Banker Chemical Co., Phillipsburg, N. J., with headquarters at 17 East 42nd Street, New York City.

G. N. SCHRAMM has been appointed on the chemical staff of the Bureau of Standards to assist in the work of the battery and electrochemical section. He will be engaged on various research problems under the general direction of George W. Vinal, chief of this section of the Bureau.

E. G. SIEVERS, who has been in charge of the U. S. Geological Survey statistical and geologic work on natural gas and natural-gas gasoline, has been transferred from the Survey to be an assistant valuation engineer in the Oil and Gas Section of the Bureau of Internal Revenue. Mr. Sievers began work in his new position on July 10.

Obituary

EDWARD R. CALDWELL, president of the Syracuse Rubber Co., Syracuse N. Y., died July 6 at his residence. He was the founder of the Caldwell & Ward Brass Co. and for many years was head of the E. R. Caldwell & Son Brass Co. He was one of the founders of the Syracuse Rubber Co., which manufactures rubber tires.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

The Recent Trend of Wholesale Commodity Prices

Closing Up the Spreads Between the Great Groups of Commodities—Further Advances Predicted by Business Cycle Students

SINCE January there has been an upward swing in general wholesale prices which has done much to correct the maladjustment in the price levels of individual commodities. During 1921 the free interchange of commerce had been considerably restricted by the false relations between the prices for the products of the different industrial groups. The higher prices for agricultural and food products, metals and other basic materials of commerce have greatly improved although not entirely eliminated this unfavorable economic condition.

The newly revised index number of the Federal Bureau of Labor Statistics for all commodities, about which we shall have more to say later, has risen from 138 in January, 1922, to 148 for May. Farm products have shown a similar gain of 10 points and foods, fuel and building materials have all recorded improvement. Bradstreet's monthly index during the past thirteen months has advanced eleven times and decreased only twice and then to a minor extent. Dun's index, too, has steadily risen during the past eleven months. *Chem. & Met.'s* weighted index of chemical prices, which stood at 143.30 on January 1, 1922, averaged 157.48 for the month of June and 154.65 for the past week.

That the upward trend of wholesale commodity prices will continue for several months at least is the conclusion drawn by the Harvard Economic Service from a study of price movements over a number of years. This is confirmed, they believe, by the fact that "fundamental economic conditions are still favorable to continued price advance."

The Harvard Service's curve which is reproduced in Fig. 2, is based on their ten-commodity index, which started its upward movement last September and since April has risen steadily. The Harvard forecast for continued price advance is based on the following data and conclusions:

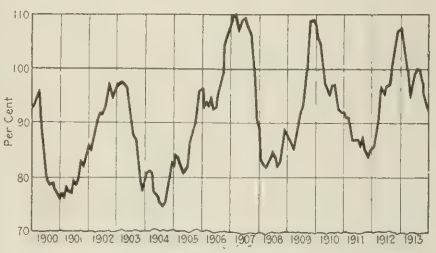

FIG. 2—HARVARD ECONOMIC SERVICE'S TEN-COMMODITY INDEX, 1900-1913

> There have been four major upswings in prices from 1900 to 1913. These movements are shown in the accompanying chart (Fig. 2) where the ten-commodity index is plotted for this period. The first rise begin in January, 1901, and lasted for 21 months, the second commenced in September, 1904, and continued for 30 months; the third started in September, 1908, and terminated 14 months later; and the fourth continued for 14 months beginning in November, 1911. Thus the minimum duration of price advance was 14 months.
>
> The index number of the Bureau of Labor Statistics shows even longer periods of advance. Beginning in June, 1901, the upward movement continued for 20 months; the next advance started in October, 1904, and lasted for 36 months; the third upward movement commenced in August, 1908, and lasted for 19 months; the last advance during the period considered began in May, 1911, and lasted for 29 months. When we consider that the present rise of prices has been under way for only 10 months, according to the ten-commodity index, the evidence from former business cycles points definitely to a continuance of the present upward movement.

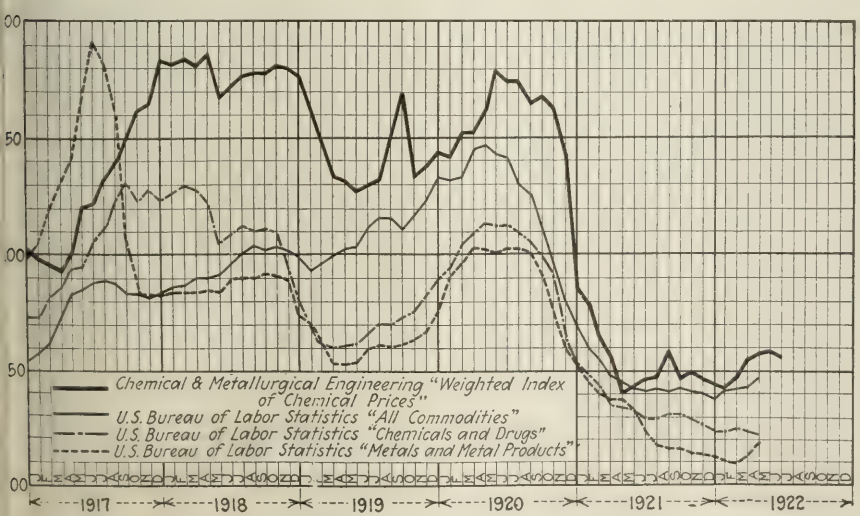

FIG. 1—"CHEM. & MET.'S" INDEX OF CHEMICAL PRICES AND THE U. S. BUREAU OF LABOR STATISTICS' REVISED INDEX NUMBERS, 1917-1922

The Revised Index Numbers

As reported in our issue of July 5 the Bureau of Labor Statistics has recently announced a complete revision of its series of index numbers showing changes in the level of wholesale prices. This revision consists of (1) a regrouping of the commodities and the addition of a considerable number of new articles and (2) the use of the 1919 census data for weighting purposes in place of the 1919 census data formerly employed.

In preceding reports the Bureau confined an article to a particular group regardless of its fitness for inclusion also under other group designations. Under the new plan, articles properly falling under more than one of the classifications adopted are to be included under each classification. In computing the general index number

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	154.65
Last week	156.67
July, 1921	148
July, 1920	274
April, 1918 (high)	286
April, 1921 (low)	140

The decided drop in this week's index number is almost entirely attributable to the lower prices for cottonseed oil. Formaldehyde also declined—to the lowest level since the war—and so did caustic soda. The only increases were for linseed oil and acetic acid.

TABLE I—REVISED INDEX NUMBERS OF WHOLESALE PRICES, BY GROUPS OF COMMODITIES, AND BY MONTHS, SINCE JANUARY, 1922.

1913 EQUALS 100

1922	Farm Products	Foods	Cloths and Clothing	Fuel and Lighting	Metals and Metal Product	Building Materials	Chemicals and Drugs	House Furnishing Goods	Miscellaneous	All Commodities — New Index	All Commodities — Old Index
Jan.	122	131	176	195	112	157	124	178	117	138	148
Feb.	131	135	174	191	110	156	123	177	117	141	151
Mar.	130	137	172	191	109	155	125	175	117	142	152
Apr.	129	137	171	194	113	156	124	175	116	143	152
May	132	138	175	216	119	160	122	176	116	148	...

for all commodities, however, such articles will be counted only once, in order to avoid duplication in the final result.

Table I gives the revised index numbers for the several commodity groups from January to June of the current year. For comparison with the new series, the old general index of all commodities is shown in the last column.

Weighting of Chemicals

The former index number for the group "Chemicals and Drugs" was based on the wholesale prices in New York for acetic acid, muriatic acid, nitric acid, sulphuric acid, grain alcohol, wood alcohol, lump alum, anhydrous ammonia, borax, copper sulphate, refined glycerine, opium, quinine, carbonate of soda, caustic soda, nitrate of soda, soda ash and crude sulphur. To show the great number of additions made in connection with the current revision as well as relative weightings given the individual commodities, Table II is appended.

The weighting factors are taken from the 1919 census, supplemented in some instances by information from other government sources and from trade associations. In each case the figures represent, as nearly as can be determined, the quantity of the article sold in the markets in 1919. For commodities represented by more than one series of price quotations, the total quantity marketed has been apportioned among the several markets or grades of the commodity in proportion to their relative importance.

TABLE II. WEIGHTING FACTORS USED BY BUREAU OF LABOR STATISTICS IN CONSTRUCTING ITS INDEX NUMBERS FOR "CHEMICALS AND DRUGS"

Commodity	Unit	Weighting Factor—(000 omitted)
(a) *Chemicals*:		
Acids, New York—		
Acetic, 28 per cent	lb.	53,084
Muriatic, 20 deg.	lb.	294,260
Nitric, 42 deg.	lb.	38,880
Stearic, triple pressed	lb.	16,970
Sulphuric, 66 deg.	lb.	6,592,540
Alcohol, New York—		
Denatured, No. 5, 188 proof	gal.	60,399
Wood, refined, 95 per cent	gal.	6,985
Alum, lump, New York	lb.	654,000
Ammonia, anhydrous, New York	lb.	54,700
Bleaching powder, New York	cwt.	1,771
Borax, crystals and gran., N. Y.	lb.	42,870
Copper sulphate, 99 per cent, crystals, N. Y.	lb.	35,288
Copra, South Sea, sun dried, N. Y.	lb.	98,561
Formaldehyde, New York	lb.	19,664
Oil, vegetable—		
Coconut, crude, Pacific Coast	lb.	244,325
Corn, crude, in barrels, New York	lb.	13,636
Palm kernel, crude, New York	lb.	41,564
Soya bean, crude, in barrels, N. Y.	lb.	88,987
Tariffs of, arsenic, 88-92 per cent, N.Y.	lb.	12,625
Salsoda, New York	cwt.	1,437
Soda ash, 58 per cent, light, N. Y.	cwt.	20,670
Soda, bicarbonate, Amer., f.o.b. wks.	lb.	283,120
Soda, caustic, 76 per cent, solid, N.Y.	lb.	638,980
Soda, silicate of, 40 deg. N. Y.	cwt.	5,736
Sulphur, crude, New York	gross tons	678
Tallow, inedible, packers' pr., Chicago	lb.	263,951
(b) *Fertilizer materials*:		
Acid phosphate, 16 p.c., bulk, N.Y.	tons	3,680
Ammonia, sulphate, dbl. bags, N.Y.	cwt.	5,950
Ground bone, steamed, Chicago	tons	60
Muriate of potash, 80-85 per cent, bags, New York	tons	21
Phosphate rock, 68 per cent, f.o.b. mines	tons	2,272
Soda nitrate, 95 per cent, New York	cwt.	8,978
Tankage, 9 and 20%, crushed, f.o.b. Chicago	tons	297
(c) *Drugs and pharmaceuticals*:		
Acid, citric, domestic, crystals, N.Y.	lb.	3,164
Acid, tartaric, crystals, U. S. P., N. Y.	lb.	5,313
Alcohol, grain, 190 pr., U.S.P., N.Y.	gal.	25,000
Cream of tartar, powdered, N. Y.	lb.	2,855
Epsom salts, U.S.P., in barrels, N.Y.	cwt.	587
Glycerine, refined, New York	lb.	64,343
Opium, natural, U.S.P., New York	lb.	619
Peroxide of hydrogen, 4-oz. bottles, New York	gross	875
Phenol, U. S. P., New York	lb.	64,300
Quinine, sulphate, mfrs' quo., N. Y.	oz.	3,937

The New York Market

New York, July 17, 1922.

Activity in the chemical market during the past week was along very limited lines which, of course, is not unusual at this time of the year. Producers in many items are resuming the old tactics of price cutting in a vain effort to clear out surplus stocks. A few price changes were the only features of the interval. The most important of these was the sharp cut in the price of formaldehyde to the lowest level recorded since the war. The export movement in caustic soda remained very slow and prices for standard goods were again fractionally lower. Leading factors are of the opinion that the present financial uncertainty of Germany, together with the fluctuating foreign exchange, are directly responsible for the decline. The domestic market however, was decidedly active among first hands.

In contrast with these declines was an advance in white arsenic. Insecticide manufacturers have resumed buying and spot supplies have become very scarce with prices advanced to 7¾c. per lb., a new high level for the year. Copper sulphate has remained in an exceptionally tight condition, and it is doubtful if large quantities can be had for earlier than September shipment.

General and Special Chemicals

Acetate of Soda—Prices continue firm on spot goods and the market appears to be in limited supply. Dealers quote 6¼@6½c. per lb. on spot, with material at the works ranging from 5¾@6c. per lb.

Bichromate of Soda—Prices are reported around 6¾@7c. per lb. The general inquiry has remained somewhat dormant, with operations mostly

Caustic Potash—Recent German ar rivals have tended to weaken the mar ket considerably. Offerings of 88@9 per cent are heard at 5½@5¾c. per lb

Caustic Soda—Leading producers re port the export market rather eas with prices around $3.55@$3.60 per 10 lb., f.a.s. July shipment. The domesti market is steady at 3¾c. per lb. fo standard brands of goods. Producer report a regular call for contracts.

Chlorate of Potash—Imported mate rial has been in fair demand durin the past week, with prices firmly main tained at 6½c. per lb. Domestic produc ers quote 8c. per lb., f.o.b. works.

Formaldehyde—Market inactivity i this product are the direct cause o sharp price reductions among large producers. In some quarters as low as 7½c. per lb. was heard. The resale market for spot goods was held around 8c. per lb.

Fusel Oil—Factors in the crude product quote $1.45@$1.50 per gal. The refined grade is held around $2.25@$2.50 per gal.

Epsom Salt—U. S. P. heavy spot stocks of imported material are keep ing second-hand figures down around $1.85@$2.00 per 100 lb. Producers quote prices around 2½c. per lb. De mand is moderate for small lots.

Oxalic Acid—The market among re sale merchants is held in a firm posi tion, with moderate quantities sold a 14¾c. per lb. Producers quote limited amounts at 14½@14¾c. f.o.b. works.

Prussiate of Soda—Imported spo goods were reported lower with quota tions ranging from 20½@21c. per lb Small lot trading was the only feature of the market with the general tone rather unsteady.

Vegetable Oils

Cottonseed Oil—The market was sub jected to severe pressure when th crude material fell off considerably Trading was active at the low figure many buyers taking immediate advan tage of the saving. Crude oil for im mediate shipment from the Southeas was quiet at 8½c. per lb. Septembe shipment sold at 8¾c. per lb buyers tanks, f.o.b. mills. Bleachable oil wa offered at 10c. per lb., buyers' tanks f.o.b. N. Y.

Linseed Oil—The general tone of th market was quite active for this mate rial, advancing from 1 to 2c. per ga During the later part of the week lead ing crushers were asking 89c. per ga with several lots quoted up to 90c. A moderate buying interest was noted fo foreign oil in nearby positions. Sale of July shipment were reported at 82 per gal., c.i.f. N. Y.

Castor Oil—The market remained i a steady position during the week an producers quoted No. 3 grade at 11 per lb. with A. A. in barrels at 12 per lb.

Corn Oil—The market for crude ma terial in barrels was unchanged a 11½@11¾c. per lb. The demand wa

The Chicago Market

CHICAGO, July 13, 1922.

The industrial chemical market showed but little change during the past two weeks except for a slightly firmer tone. Buying continued to be on a hand-to-mouth basis although repeat orders were reported to be more numerous. The railroad strike has had but little effect on the market, as freight is apparently moving as before. Prices are rapidly becoming more stable and with a few exceptions there was but little cutting. Factors in the chemical market were evidently satisfied with the volume of business they were doing and offered no complaints.

General Chemicals

During the past two weeks but little change was to be noted in the general condition of the alkali market. A routine demand existed for *caustic soda* with the solid quoted at $3.85@$3.95 per 100 lb. and the ground at $4.35@$4.50, basis 76 per cent. *Caustic potash* was reported to be moving only in small parcels at 6¼c.@6½c. per lb. for the imported 88 to 92 per cent material. *Soda ash* moved in the regular channels in small or moderate quantities at $2.20@$2.30 per 100 lb. for 58 per cent material in cooperage.

Alums were a trifle easier with spot stocks somewhat heavier. *Ammonia alum* was quoted by importers or their agents at 3¾c.@4¼c. per lb. for the lump and 4¼c.@4¾c. for the powdered. *Potash alum* was unchanged at 4½c.@5c. per lb. for the iron free lump and 5½c.@6c. for the U. S. P. powder. *Sal ammoniac* was quiet and only small lots moved at 7¾c.@8c. per lb. on the white granular. Barium compounds were firm and domestic makers were in a position to deliver ordinary lots at once. *Barium carbonate* was rather quiet with small supplies available at 5c.@5½c. per lb. *Barium chloride* was in better demand and was offered at $95@$110 per ton. *Copper sulphate* continued firm and scarce with only small supplies available at 6½c.@7c. per lb. *Carbon bisulphide* was very active and scarce although today supplies were reported to be larger. Dealers were asking 7c.@7½c. per lb. for small or moderate lots. *Carbon tetrachloride* was rather slow and supplies were heavy. Large drums were available at 10c.@10½c. per lb. *Formaldehyde* was dull with stocks moving very slow at 9c. per lb. for single barrels. *Furfural* lacked quotable change at 35c. per lb. for 1,000 lb. lots or over.

Glycerine was rather easy with refiners quoting c.p. material in drums at 15c. per lb. *Red phosphorus* enjoyed a fair demand and was quoted by second hands at 26c.@30c. per lb. for case lots.

Bichromates were dull and unchanged with weak holders ready to cut prices for any business in sight. *Potassium bichromate* was available at 11c. per lb. in single cask lots and similar quantities of the soda at 8½c.@9c. *Red prussiate of potash* was still very scarce with broken lots quoted at 90c.@$1 per lb. *Yellow prussiate of potash* was easier and supplies were more plentiful at 32c.@35c. per lb. *Potash permanganate* was weaker with supplies of foreign material very plentiful at 15½c.@16c. per lb. for U. S. P. small crystals. *Hyposulphite of soda* moved in a routine way to the consuming trade at $3.85 per cwt. for the pea crystals in barrels. *Zinc chloride* was quoted lower at 6½c.@7c. per lb. for the granular.

Linseed oil was reported by a prominent factor to be moving very well to the consuming trade. The boiled oil was quoted late today at $1.03 per gal. in single drum lots with similar quantities of the raw at $1.01.

Turpentine was reported to be moving slowly and one factor advised his customers to hold off if at all possible as lower prices were expected. Single drum lots were quoted today at $1.31 per gal. but the movement was very light.

The Iron and Steel Market

PITTSBURGH, July 14, 1922.

While the finished steel markets are quieter, as to actual tonnage turnover, the general standing of the market, particularly as to prices, appears to be firmer on account of the fresh menaces to production that have developed in the past week or two. It may be considered objectionable that the strength of the market should be in inverse ratio to the efficiency with which the plants operate, but conditions have to be taken as they are found.

Before the railroad shopmen's strike began July 1 there was congestion at several points where large tonnages of non-union coal were to be moved, and this condition has since been accentuated, presumably chiefly on account of the strike. Large quantities of both West Virginia and Kentucky coal, much of it consigned to byproduct coking plants, have accumulated. Coal has become much scarcer, but the increased scarcity is to be attributed chiefly to railroad conditions, not to the coal strike.

Steel Production

Prospects are that unless there is a great improvement very soon in fuel supplies the production of pig iron and steel will be curtailed from the rate recently prevailing. This rate, moreover, has not been altogether as great as has been estimated recently, it being necessary, in the light of later reports, to revise estimates. The rate of steel ingot production was about 35.500,000 tons a year in April, 36,400,000 tons in May and 36,600,000 tons in June. There had been a sharp increase in production in the first three months of the year but since April 1, when the coal strike started, there has been very little increase.

The Steel Corporation's unfilled obligations increased by 602,769 tons in April, 157,311 tons in May and 381,403 tons in June. Shipments were at about 70 per cent of capacity in April and 75 per cent in both May and June. Thus bookings were much heavier in June than in May. The total of unfilled obligations at the end of June was 5,635,631 tons, but the actual figure sometimes means practically nothing as to operating prospects, the point being whether the tonnage is in contracts or in actual shipping orders. June 30, 1921, the unfilled obligations amounted to 5,117,868 tons, or only a trifle less than at present, but the corporation operated at only 25 per cent in July. Now it is operating at about 75 per cent and its shipping orders would call for a still higher rate. In actual orders the corporation is sold up for about three months.

The Market Situation

Neither sellers nor buyers seem disposed to commit themselves for the last quarter of the year, and thus the market in that respect cannot be regarded as either strong or weak. In the matter of early deliveries there is some demand, with little unsold steel available, and in that respect the market is in sellers' favor. However, in most lines the early deliveries are commanding premiums, bars, shapes and plates for instance being at 1.70c., 1.75c. or 1.80c., according to details of order. This gives the steel market a superficial appearance of great strength, but experience indicates that too much reliance may easily be placed upon such a showing. If the premiums come off, later, the market is made to look weaker and buyers become alarmed, while should plates, shapes and bars advance to 1.80c. as a price for any delivery buyers would in all probability consider the price too high and would start another liquidation of all stocks.

It is rather a complication that just at this time, when coke supplies, previously increasing, are menaced, pig iron should show a softening tendency in some districts. Basic iron at valley furnaces has become quotable at $24, against $25 ruling for more than two months, and southern iron is off a dollar a ton. What will come of this curious situation remains to be seen. Furnaces frankly admit that buyers are showing much less interest in pig iron than it was expected they would be showing by this time. Consumption has evidently been less than was counted upon, in the case both of foundries and of steel works that do not make their pig iron themselves.

The scrap market has been turning softer in the past fortnight in several districts. The theory in the scrap market for two or three months past has been that scarcity of coke makes for higher scrap prices, by both blast furnaces and steel mills using more scrap. Heavy melting steel ruled strong at $17.50, delivered Pittsburgh district, during May and June, but in the past few days round lots have been offered mills at $17 without finding takers.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The plant and business of the San Nox Chemical Co., has been acquired by Charles Siegel and associates from James Johnston and H. H. Smithson, heretofore heads of the company. The company specializes in the manufacture of liquid soaps, polishes, etc. and the new owners plan for immediate extensions and improvements to approximately double the present capacity. New equipment will be installed.

Arizona

SUPERIOR—The Magma Copper Co. has completed plans and will commence the immediate construction of its proposed new smelting plant, estimated to cost in excess of $500,000, including machinery. Contract for the steel framework for the building recently has been awarded.

Arkansas

WESSON—The Edgar Lumber Co. has tentative plans under consideration for the construction of a new creosoting plant.

PENTERS BLUFF—The American Manganese Co. has acquired about 1,200 acres of land in Independence County with manganese and phosphate deposits, and plans for extensive development work. A plant will be installed for immediate production from a portion of the tract.

California

SANTA CLARA—The National Stone Tile Co., San Francisco, is negotiating with the local Chamber of Commerce for a suitable site for the erection of a new plant. Plans will be prepared at an early date.

YUBA CITY—The Shell Oil Co., 343 Sansome Street, San Francisco, will soon commence the erection of a new local distributing plant, with equipment to provide for refined oils, lubricating oils and various byproducts. The plant will cost in excess of $30,000.

Florida

TAMPA—The Riggs Chemical Laboratories are perfecting plans for extensive manufacture at their plant, and facilities will be provided for the production of a line of chemicals and byproducts. Walter B. Riggs and Theodore A. Bailey head the company.

Illinois

WAUKEGAN—The City Council is having plans completed for the construction of a new filtration plant at the municipal waterworks. With pumping station and intake, the proposed plant will cost about $950,000. Hood, Decker & Drury, 303 South State St., Ann Arbor, Mich., are engineers.

PINCKNEYVILLE—The Atlas Powder Co. Delaware Trust Bldg., Wilmington, Del., has plans under way for the erection of a new local plant to consist of a number of 1-story buildings, estimated to cost about $100,000, including equipment. L. K. O'Brien is engineer in charge.

Indiana

ANDERSON—The National Tile Co. will commence the immediate rebuilding of the portion of its plant, destroyed by fire, June 28, with loss estimated at about $40,000.

SCOTTSBURG—The plant of the J. W. P. Tire Co., defunct, with four acres of land, has been acquired by Clay Prosser and associates from the receiver, M. E. Smith. No announcement has as yet been made regarding the plans of the new owners.

Maine

MINOT—The Rogers Fibre Board Co., is planning for the rebuilding of the portion of its plant, including power house, dam-

Maryland

BALTIMORE—The Republic Gasoline Co., 308 Marine Bank Bldg., recently organized, is planning for the establishment of a plant in Kentucky, on site to be selected, for the manufacture of carbon black and affiliated specialties. G. I. Stafford is president, and C. R. Rishel, vice-president.

WILLIAMSPORT—The Conococheague Brick Co. is planning for enlargements in its plant, to include a new building for general manufacture and 3 kilns. The work is estimated to cost about $35,000.

FROSTBURG—The Frostburg Sewer Pipe Co., care of T. C. Carrington, secretary, Frostburg Commercial Club, has acquired a tract of land of about 33 acres, previously held by the Consolidation Coal Co., as a site for the erection of its proposed new plant for the manufacture of vitrified clay sewer pipe. Plans are being drawn for the initial buildings and it is planned to commence erection at an early date. The company was organized recently with a capital of $200,000.

BALTIMORE—The Water Bureau, William A. Megraw, water engineer, City Hall, will soon call for bids for the construction of the proposed new filtration plant at the city water works, to be 1-story, 245x295 ft., estimated to cost close to $1,000,000. William W. Emmert, Union Trust Building, is consulting engineer.

Massachusetts

WOLLASTON—Fire, July 1, destroyed one of the buildings at the plant of the Norfolk Varnish Co., Arlington St., with loss reported at about $10,000. The structure will be rebuilt.

CAMBRIDGE—The Cambridge Rubber Co., 148 Main St., has filed plans for the construction of a new 1-story building at its works.

MALDEN—The Potter Drug & Chemical Corp. has tentative plans under consideration for the enlargement of its local plant, used primarily for the manufacture of soap products. It is proposed to discontinue the present London, Eng., factory, established during the war period and remove the equipment to the Malden plant, where all foreign production will be handled in the future.

SPRINGFIELD—The Springfield Gas Light Co., 35 State St., will construct a new holder and auxiliary plant on Page Blvd., to cost about $240,000. Contract for the holder has been awarded to the Bartlett, Hayward Co., Baltimore, Md.

Michigan

ESSEXVILLE—The Aetna Portland Cement Co., 412 Union Trust Bldg., Detroit, is completing foundation work for a number of buildings at its proposed local plant and will soon commence superstructure work. The plant will cost close to $1,000,000, including machinery.

RIVER ROUGE—The Detroit Sand Lime Brick Co., 1008 Vinton Bldg., Detroit, has commenced excavations for the initial building at its proposed local plant, on site recently acquired. The works are estimated to cost in excess of $75,000.

Missouri

POPLAR BLUFF—The Poplar Bluff Rubber Co. has secured a local building and plans for the immediate installation of equipment for the manufacture of rubber specialties. John H. Patterson is president and manager.

ST. LOUIS—The Mallinkrodt Chemical Works, Inc., 3600 North 2nd St., is reported to be planning for enlargements in its plant. The company recently increased its capital to $5,000,000. Edward M. Mallinkrodt is president.

ST. LOUIS—Machinery to cost about $30,000, will be installed in the proposed new plant to be constructed by the Superior Folding Box Co., 2311 Chestnut St. at Geraldine Ave. and Penrose St. The entire

Nebraska

OMAHA—The Standard Chemical Mfg. Co., 1310 Harney St., has construction under way on a new 2-story plant, 60x114 ft., on Leavenworth St. near 41st St. Charles M. Nye, 737 Peters Trust Bldg., is architect.

New Jersey

NEWARK—The Chemical Treatment Co. has leased property at 264 Jelliff Ave., comprising a 3-story and basement building, aggregating about 13,000 sq.ft., and adjoining property, 105x250 ft., for the establishment of a new plant for the manufacture of special chemical products. It is planned to commence the erection of a new building at an early date on the available vacant land.

PERTH AMBOY—The Novo Laboratories, Inc., manufacturers of chemical specialties, has commenced the construction of a new building at its plant No. 3.

GLOUCESTER CITY—The Armstrong Cork Co., South Camden, manufacturer of cork board and cork insulation products, has acquired the plant of the Ancona Co., Gloucester City, heretofore, used by the Welsbach Co., manufacturer of gas mantels, etc., for a consideration said to be $275,000. Adjoining property at Kings and Essex Sts., has also been purchased. The new acquisition will be used as an extension.

New York

NIAGARA FALLS—The Defiance Paper Co., Walnut Ave., has broken ground for the construction of a 1-story addition, 50x200 ft., at Third and Walnut Sts., estimated to cost approximately $200,000, with machinery.

NEW YORK—The Mexican Petroleum Co., 120 Broadway, has commenced work on extensions and improvements at its oil terminal and distributing plant at Mata Rodonda, Mex., to cost about $300,000.

NEW YORK—The American Glass Bottle Co., 1179 Union Ave., has filed plans for the construction of a 1-story building, 65x79 ft., to cost about $12,000.

NIAGARA FALLS—The Kimberly & Clark Co., manufacturer of paper products, has foundation work under way for a 2-story addition to its local plant on the Niagara Falls Blvd., 60x100 ft. It is purposed to push the structure to completion for earliest possible occupancy.

North Carolina

CANTON—The Champion Fibre Co. is arranging for the early occupancy of its new local plant, now nearing completion, for the manufacture of paper products. The mill will represent an investment of about $1,000,000, and will use three chemical processes for the utilization of paper pulp.

Ohio

COLUMBUS—The Brown Steel Co., 480 Neilston St., manufacturer of steel products, will commence the immediate construction of a 1-story plant addition, 275x305 ft., estimated to cost approximately $150,000, with equipment. Charles W. Brown is general manager.

AKRON—The Anaconda Copper Co., 25 Broadway, New York, N. Y., has purchased property at Betts Corner, Akron, comprising about 9 acres of land for its proposed new plant, for the manufacture of zinc oxides and kindred specialties. Plans for the initial buildings are under way and it is expected to commence construction in September. The plant will be operated by the International Lead Co., a subsidiary organization. It is estimated to cost approximately $1,000.000, with machinery.

BEDFORD—The Mason Tire & Rubber Co., Kent, Ohio, has acquired the plant and property of the Owen Tire & Rubber Co. at Bedford, from Carl E. Friedolin, referee in bankruptcy, for a consideration of about $275,000. The plant is located on a 14-acre tract of land, and consists of a number of buildings. It will be used by the new owner for the manufacture of automobile tires and it is expected to develop an immediate capacity of 1,500 tires per day giving employment to about 200 operatives. The output will be increased in the near future, and the working force enlarged to close to 500 employees. O. M. Mason is president.

YOUNGSTOWN—The Youngstown Steel Co. will soon commence the construction of a new mechanical puddling plant, estimated to cost about $1,500,000. The mill will be operated under a new process and will

develop an output of about 250 tons of iron per day, giving employment to about 200 men. A blast furnace of about 500-ton capacity will be constructed in the near future.

Oklahoma

SAND SPRINGS—A new 1-story foundry building will be constructed by the Tulsa Stove & Foundry Co., Tulsa, Okla., in connection with its proposed local plant, estimated to cost about $175,000.

Pennsylvania

HIGH SPIRE—The Keystone Carbonic Gas Co. has broken ground for the construction of its proposed local plant, 60x140 ft., for the manufacture of carbonic gas and other commercial gas products, estimated to cost close to $250,000. S. S. Bailey, Security Trust Bldg., Harrisburg, Pa., is president.

PITTSBURGH—The Atlantic Refining Co., Chamber of Commerce Bldg., has acquired property in the Lawrenceville district, approximating 7½ acres of land bounded by 56th and 57th Sts. and the Allegheny River, in the vicinity of its present works, for a consideration of $350,000. It will be used for the construction of a new refinery addition.

WAYNESBORO—The Frick Co. will soon take bids on separate contracts for the erection of a 1-story foundry, 300x600 ft., estimated to cost about $200,000, with machinery. A. J. Frick is vice-president.

WILLIAMSPORT—The plant and property of the Nordmont Chemical Co., Nordmont, near Williamsport, devoted to the manufacture of wood alcohol, carcoal, and by-products, has been acquired by new interests, headed by Charles W. Jones, Williamsport. The plant will be continued in operation for a certain time, and later will be dismantled, the machinery to be removed to another location.

MORRISVILLE—The Robertson Art Tile Works has construction under way on a new 1- and 2-story building at its plant, 110x160 ft., to be used for general production and operations.

South Carolina

HAMBURG—The Hankinson Brick Co. is said to be planning for the rebuilding of the portion of its plant, including kilns, destroyed by fire June 30. An official estimate of loss has not been announced.

Texas

STAMFORD—The Williams-Miller Gin Co., Elks City, Okla., operating cotton gineries, is planning for the construction of a new cotton oil mill on property at Stamford, estimated to cost about $150,000.

LLANO—The Honey Creek Minerals Co. has plans under way for the construction of a new refining plant and laboratory at its molybdenite ore properties, estimated to cost about $150,000. The company will also install considerable new machinery in different departments of its works to cost approximately $100,000.

DALLAS—The Taxa Cola Co. of America, recently organized under Delaware laws, with a capital of $2,000,000, has plans under way for the construction of a 2-story plant on local site, for the manufacture of extracts. It is also proposed to construct a number of branch plants in different cities of the state, and sites have been selected at Galveston and Mexia. John H. Wood, Dallas, is secretary and acting treasurer in charge.

Washington

SEATTLE—The Washington Iron Works, Seattle Blvd., and Norman St., will construct a 1-story foundry, 130x140 ft., in connection with a number of plant additions, estimated to cost about $500,000. The foundry will be used for the production of steel and grey iron castings. Gerald Fink is president.

West Virginia

HUNTINGTON—R. E. Morrison, Huntington, is organizing a new company with capital of $50,000, to construct and operate a local plant for the manufacture of soap products. A site is being selected and erection will be commenced at an early date.

Canada

THREE RIVERS, QUE.—The Three Rivers Pulp & Paper Co. is said to have preliminary plans in progress for the construction of a new mill on local site, estimated to cost close to $2,500,000, with machinery

New Companies

THE UNITED STATES PAPER CO., Jersey City, N. J., has been incorporated with a capital of $100,000, to manufacture paper products. The incorporators are Robert P. Gilman, J. Frank Finn, and Frank W. Hastings, Jr., 15 Exchange Place, Jersey City.

THE PENNSYLVANIA POTASSIUM PHOSPHATE CO., Philadelphia, Pa., is being organized by Frank V. McMullin, Harrison B. Price and Edwin Smiley, all of Philadelphia, to manufacture phosphatic and other fertilizer and chemical products. Application for a state charter will be made on July 24. The company is represented by Joseph R. Embery, 1105-6 Real Estate Trust Bldg., Philadelphia.

THE LEAD KOTE PROCESS, INC., New York, care of Slade & Slade, 200 Broadway, representatives, has been incorporated with a capital of $100,000, to manufacture galvanizing products for steel treatment. The incorporators are M. Robinson, I. Levin and L. C. Brady, all of New York; the company will operate a local plant.

THE LOUIS ROSE BRICK CO., Highland Park, Mich., has been incorporated with a capital of $100,000, to manufacture brick and other burned clay products. The incorporators are John P. Scallen, George W. Handloser, and Louis Rose, 169 Eason Ave., Highland Park.

THE HUB PAINT REMOVER CO., Boston, Mass., has been incorporated with a capital of $50,000, to manufacture paint removers and other chemical products. Reuben Hall, 70 State St., Boston, is president and treasurer; Alfred Hall is vice-president.

THE MAURICE CHEMICAL CO., 1545 South Charles St., Baltimore, Md., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture refractory cements, glazing materials, etc. The incorporators are F. Howard Kidd, W. Frank Reed and Joseph R. Hudson.

THE GRISWOLD OIL CORP., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $15,000,000, to manufacture petroleum products.

THE PERTH AMBOY CO., 303-5 Front St., Perth Amboy, N. J., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by Arden D. Cline and Willis H. Landis, Elizabeth, N. J. The last noted represents the company.

THE ORLANDO PERFECT PRODUCTS CO., Jacksonville, Fla., has been incorporated with a capital of $100,000, to manufacture fertilizer products. F. E. Clark is president; A. L. Morgan, vice-president; and E. W. Mitchell, secretary, all of Jacksonville.

THE ELLIOTT PETROLEUM CO., Los Angeles, Calif., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are J. E. Elliott, Floyd C. Merritt and M. E. Davis, all of Los Angeles; and A. M. Goodhue, Long Beach, Cal. The last noted represents the company.

THE MILLARD LEATHER CO., Attleboro, Mass., has been incorporated with a capital of $80,000, to manufacture leather products. Harry S. Millard is president; and Karl B. Brooks, Attleboro, treasurer.

THE MET-ARBOR CO., Norwalk, Conn., has been incorporated with a capital of $50,000, to manufacture soaps, chemicals, etc. The incorporators are William Krusch, Coleburn Block, F. J. G. Hardy and W. T. Krusch, all of Norwalk.

F. BREDT & CO., INC., New York, care of F. S. Rauber, 38 Park Row, representative, has been incorporated with a capital of $50,000 to manufacture chemicals and chemical byproducts. The incorporators are G. C. Orth, H. A. Fanning and L. B. Lebowitz.

THE PENETRATOR CO., INC., Lakewood, N. J., has been incorporated with a nominal capital of $2,000, to manufacture oils, compounds, etc. The incorporators are Max Jerry, M. E. and John A. Meyers, 215 4th St., Lakewood.

THE ELECTROCAST STEEL FOUNDRY CO., 920 West Kinzie St., Chicago, Ill., has been incorporated with a capital of 300 shares of stock, no par value, to manufacture steel castings. The incorporators are Alfred Johnson, Daniel B. Abrahamson and Adolph J. Peterson.

THE HANNIGAN WATER PROOFING & MFG. CO., Milford, Conn., care of Woodburn Martin, Georgetown, Del., representative, has been incorporated under Delaware laws with capital of $50,000, to manufacture waterproofing products and affiliated specThomas Hannigan, and L. U. Berger, all of Milford.

THE LESLIE GROVE OIL CO., Newark, O., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are Leslie Grove and Calvin C. Jeffries, both of Newark.

THE PIED PIPERS OF AMERICA, INC., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The company is represented by M. A. Vogel, 291 Broadway. The incorporators are D. A. Bach, and W. S. Patjans.

THE CALIFORNIA-MAINE OIL CO., Portland, Me., care of M. F. Foster, Portland, representative, has been incorporated with a capital of $1,000,000, to manufacture petroleum products. R. L. Johnson is president; and A. B. Farnham, treasurer.

THE DOMINION PORTLAND CEMENT CO., care of the Delaware Registration Trust Co., 900 Market St., Wilmington, Del., has been incorporated under Delaware laws, with a capital of $2,000,000, to manufacture portland cement.

THE KLENNIT-CHEMICAL CO., Fort Worth, Tex., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are L. W. Bevans, L. D. Patterson and T. B. Yarborough, all of Fort Worth.

THE ROGERS ASBESTOS CO., Houston, Tex., has been incorporated with a capital of $40,000, to manufacture asbestos products. The incorporators are E. M. Rogers, W. W. Bates and S. H. Rudnick, all of Houston.

EISELE & CO., INC., Nashville, Tenn., care of George M. Jones, Dover, Del., has been incorporated under Delaware laws with a capital of $154,000, to manufacture chemical specialties, chemical byproducts, drugs, etc. The incorporators are A. B. Benedict, William Nelson and C. Logan Eisele, Nashville.

THE AMERICAN ROCK ASPHALT CO., Valliant, Okla., has been incorporated with a capital of $100,000, to manufacture asphalt and affiliated products. The incorporators are H. C. Clark, Valliant; Ralph P. Taylor and T. E. Webber, both of Texanna, Okla.

THE GRASS LAKE MUTUAL OIL CO., Adrian, Mich., has been incorporated with a capital of $10,000, to manufacture refined mineral oils. The incorporators are Arthur F. Messner and Warren K. Raby, both of Grass Lake, Mich.; and Rolland C. Rothfuss, 404 National Bank of Michigan, Adrian. The last noted represents the company.

THE WEST PHILADELPHIA CUT GLASS CO., Philadelphia, Pa., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $100,000, to manufacture glass products.

THE COMMERCIAL ASBESTOS CO., Seattle, Wash., care of the Commonwealth Finance Co., Securities Bldg., Seattle, representative, has been incorporated with a capital of $250,000, to manufacture asbestos products. Charles C. Franklin is the principal incorporator.

THE CARDINAL OIL CORP., Portland, Me., has been incorporated with a capital of $6,500,000, to manufacture petroleum products. R. L. Johnson is president; M. F. Foster, treasurer; and A. B. Farnham, Portland, clerk. The last noted represents the company.

THE CROCKETT COTTON OIL MILL. INC., Crockett, Tex., has been incorporated with a capital of $100,000, to manufacture cotton oil products. The incorporators are J. Legory, G. Q. King and J. S. Shivers, all of Crockett.

THE SUFFOLK LEATHER CO., INC., Boston, Mass., has been incorporated with a capital of $10,000, to manufacture leather products. Hugh J. Shaw is president and I. Stebbins Gilbert, 345 Ashmont St, Dorchester, Mass., treasurer.

THE BEATS-AWL CO., 57 Main St., East Orange, N. J., has filed notice of organization to manufacture chemical specialties, vermin exterminators, etc. Edwin S. Douglas heads the company.

THE UNITED STATES TANNING CO., Philadelphia, Pa., is being organized by A. and Nathan Rathblott, and Carl S. Gross, all of Philadelphia, to manufacture leather products. Application for a state charter will be made on July 24. The company is represented by Sundheim, Folz & Kun, 1516 Real Estate Trust Bldg., Philadelphia.

THE HINCKLEY CORP., Hinckley (Herkimer County), N. Y., care of Dunmore, Ferris & Dewey, Utica, N. Y., representative, has been incorporated with a capital of $20,000, to manufacture sulphite products. The incorporators are T. H. Ferris, F. W. New-

Capital Increases, Etc.

THE EMPIRE STATE PAPER CORP., 216 Seventh Ave., New York, has filed notice of increase in capital from $50,000 to $100,000.

Robert E. Cowden, receiver for the MASTER TIRE & RUBBER CO., Dayton, O., is arranging for the sale of the property and assets of the company, consisting of a main 1-story plant, 70x216 ft., and smaller buildings, with machinery. Bids will be received until July 26.

THE ALBANY MALLEABLE IRON CO., Albany, N. Y., has filed notice of a reduction in capital from $500,000 to $250,000.

THE HUMBLE OIL & REFINING CO., Houston, Tex., operating oil refineries, is disposing of a bond issue of $25,000,000, the proceeds to be used in part for extensions and improvements. W. S. Farish is vice-president.

THE AETNA STEEL PRODUCTS CO., 30 Church St., New York, N. Y., has filed notice of dissolution under state laws.

THE CONNECTICUT HARD RUBBER CO., New Haven, Conn., has filed notice of increase in capital from $10,000 to $50,000.

THE C. H. MILLS OIL CO., Syracuse, N. Y., has filed notice of increase in capital from $200,000 to $1,000,000, for proposed expansion.

THE B. F. GOODRICH CO., Akron, O., manufacturer of automobile tires and other rubber products, is disposing of a bond issue of $20,000,000, a portion of the proceeds to be used for extensions and improvements.

THE ZENITH FURNACE CO., Duluth, Minn., producer of pig iron, coke, etc., is disposing of a bond issue of $1,000,000, a portion of the proceeds to be used for extensions and improvements. W. B. Castle is president.

E. W. Bowen, Delphi, Ind., has been appointed receiver for the INDEPENDENT OIL CO., Delphi and Frankfort, Ind., succeeding Silas Wilson.

A merger of the MARSHALL OIL CO. and the WEST VIRGINIA PETROLEUM CO., Morgantown, W. Va., has been arranged under the first noted name. The consolidated organization will operate with a capital of $1,000,000.

Receivers for the TEXAS STEEL CO., Rusk, Tex., have made application to the District Court for permission to sell the plant and property of the company. The proposed sale will be held on Sept. 15.

The plant of the PLANTERS' COTTON OIL CO., Dallas, Tex., will be sold under foreclosure proceedings. The property represents an investment of close to $300,000.

THE UNITED STATES REFRACTORIES CO., Mount Union, Pa., has perfected arrangements for an increase in capital from $300,000 to $1,400,000.

The plant and property of the LYNCHBURG GLASS CO., Lynchburg, Va., which recently assigned, will be sold at auction for the benefit of creditors.

DWIGHT P. ROBINSON & COMPANY, Engineers and Constructors with main offices in New York City and branch offices in Chicago, Los Angeles, Montreal, Youngstown, Dallas and Rio de Janeiro, Brazil, has recently entered into a contract with the Metropolitan Life Insurance Co. by which life insurance policies are provided without expense to individuals for all members of its organization reporting to the central office under a group insurance plan. This insurance is without cost to the employees and its benefits are in addition to those provided by law under the various State Workmen's Compensation Acts. All employees included in the Plan are insured regardless of their age and condition of health and no medical or physical examination is required. The amount of insurance is increased $100 for each additional year of continuous employment and this plan of regular increase is thus a recognition of length of service.

THE ECONOMY FUSE & MFG. CO. of Chicago, Ill., announces the appointment of Charles H. Bluske as district sales manager of the Los Angeles office at 1304 Maltman Avenue. Mr. Bluske was formerly connected with the Pacific States Electric Co. of Los Angeles, and succeeds George L. Davis. The Pittsburgh Sales Office of the Economy Fuse & Mfg. Company has been moved from 2223 Farmers Bank Building to 1006 Peoples Bank Building at Fourth Ave. and Wood St.

THE U. S. ELECTRO GALVANIZING CO., Inc., announces change of name to U. S. Galvanizing & Plating Equipment Corporation, with main office and factory at 32 Stockton Street, Brooklyn, N. Y.

PAUL O. ABBE, INC., 71-73 Murray Street, New York City, announces the return of Mark L. Alden, who has been having extensive experience in the Chemical Industry for the past ten years. If his health permits him to do so, he will become the chairman of the board of directors of the company.

F. J. RYAN & Co., industrial furnace engineers, Philadelphia, Pa., held its annual meeting at the company's new offices on the 6th floor of the Wesley Building. This is the second increase of facilities of the company within the last year and a half, made necessary by the increasing amount of business. At the election of officers, F. J. Ryan was re-elected president; W. W. Posey (president of Lancaster Iron Works, Lancaster, Pa.) was elected vice-president; A. C. Scully (treasurer of Lancaster Iron Works) was elected treasurer and Miss E. N. Kraske was re-elected as secretary. S. R. Vanderbeck of Philadelphia was re-elected as director. G. F. Beach, who for a number of years had been chief engineer of the Mircs Furnace Departments of the Lancaster Iron Works and who came into a like position with the Ryan Co. after a consolidation of interests of the Mircs Co. and the Ryan Co., was retained in the same position. Additional departments have been decided upon in the line of Producer Gas and Regenerator Furnaces. This work will be under the direction of Karl G. Gustafsson, who has had considerable experience in this line of work in foreign countries, especially Germany and France. Mr. Gustafsson brings with him the results of the necessity of foreign conservation in furnace work.

Industrial Developments

CERAMIC—The Briggs Co., Lansing, Mich., manufacturer of face brick, has adopted a capacity operating schedule at its plant at Grand Ledge, Mich., on a basis of 40,000 to 45,000 bricks per day. Orders on hand insure this rate of production for a number of months to come.

The Robertson Art Tile Works, Morrisville, Pa., is running on a day and night schedule at its plant, with incoming orders in excess of production. Contracts on hand insure maximum output for some time to come.

The Model Brick Co., Houston, Tex., has placed its plant on the Crosby Road in operation, following curtailment for a considerable period. Production will be maintained for an indefinite period on a basis of 20,000 bricks per day.

RUBBER—The Hood Rubber Co., Watertown, Mass., is maintaining capacity production at its local mills, and reports orders ahead for some time to come. The sales for the first five months of the year have registered an increase of $1,200,000 in excess of those for the corresponding period of Jan. 1 to June 1, last year.

Tire production at Akron, Ohio, reached an aggregate of 2,500,000 tires at the different mills during the month of June, or a rate of 85,000 casings per day.

The Goodyear Tire & Rubber Co., Akron, Ohio, has resumed operations at its local mills, following a brief shut down for inventory. The plant will continue on a capacity basis of 26,000 casings a day.

During the month of June, the Firestone Tire & Rubber Co., Akron, Ohio, recorded the highest sales in the history of the organization. It is expected to advance the current output of 25,000 tires a day at an early date. The peak production at the plant is rated at 28,500 tires daily.

OIL—The Rex Refining Co., Sweetwater, Tex., recently reorganized under the direction of A. M. Slade, and associates, Fort Worth, Tex., has resumed operations following a shut down for more than a year past. It is expected to develop maximum production at an early date.

The Vacuum Oil Co., Paulsboro, N. J., has adopted an operating basis of close to normal at its local plant. A regular working force is being employed.

IRON AND STEEL—The Algoma Steel Co., Sault Ste. Marie, Ont., has resumed operations at two of its furnaces, and a third will be placed in service at an early date. The rail mill at the works has been placed in operation, following a period of curtailment and will be run on a capacity basis for an indefinite period.

The Republic Iron & Steel Co., Youngstown, Ohio, has resumed operations at its Bessemer plant, following a shut down for the past 18 months. About 700 men will be employed at the mill. The starting of the mill brings the Bessemer production in the valley to 100 per cent.

The Gulf States Steel Co., Birmingham, Ala., has placed its 20-inch bar mill in operation, following a shut down for about 18 months past.

The Carnegie Steel Co. has blown in the fourth blast furnace at its plant at Ness-

Castle, Pa., placing the works on a fu operating basis, with regular working forc

The Eastern Rolling Mills Co., Baltimor Md., has adopted a capacity operatin schedule at its local plant on a 24-hour p day basis, giving employment to abo 1,200 men.

New Publications

BOOKS

CHEMISCHE UNTERSUCHUNGSMETHODEN FI EISENHÜTTEN UND NEBENBETRIEBE. *Ing. Chemiker Albert Vita.* Second ar revised edition. 197 pp., 34 illustration Published by Julius Springer, Berl (1922), 78 marks (in America, $1.90).

A concise, but nevertheless thorough, con pilation of important analytical metho not only for iron and steel, but for coa gas, coal tar and its products and the mo important non-ferrous metals. It is book of handy size and is well printed ar illustrated.

"Electro Steam Boiler" is the title of pamphlet recently issued by the Electr Furnace Construction Co., Philadelphia, P

Further Investigations of Illinois Fi Clays. By C. W. Parmelee and C. Schroyer. Extracts from Bulletin No. 3 State Geological Survey, Urbana, Ill.

The *Journal of Personnel Research*, t official organ of the Personnel Resear Federation published its first issue in Ma 1922. This *Journal* publishes origin articles by workers in the biological a medical sciences, psychologists, pschiatris engineers and economists who are maki important contributions to the knowled of human beings at work and will ser men who are interested in activities th pertain to personnel in industry, commerc education and government. The magazi is published by Williams & Wilkins C Baltimore, Md.

Scovell, Wellington & Co., accountant engineers, Boston, Mass., have issued small booklet entitled "Selected Profe sional and Business Books" which contai a list of 400 books on accountancy, indu trial engineering and related busine topics. This list has proved useful to the and they think it will be helpful to anyo who is interested in building up a library.

The Hercules Powder Co., Wilmingto Del., has issued a booklet entitled "Dyn mite—The New Aladdin's Lamp." Th article was written by T. W. Bacchus, vic president of the company. It is an inte esting and accurate account of the pa played by dynamite in the industrial d velopment of this country. Copies may obtained free by addressing the Hercul Powder Co., Wilmington, Del.

THE MINING HAND BOOK OF CANAD 1922, covering the metal, mining and oil i dustries of Canada, has recently been pu lished by the Investor's Mining Hand Bo Co., Toronto, Canada. Paper bound copi are $1 and leather bound are $2 per cop

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold summer excursion meeting to Rochest Montreal, Ottawa, Kingston, Toronto, Har ilton, Niagara Falls and Buffalo, Aug. 13-1

AMERICAN CHEMICAL SOCIETY will ho its fall meeting in Pittsburgh, Pa., Sept. to 9.

AMERICAN ELECTROCHEMICAL SOCIETY w hold its fall meeting in Montreal, Sept. 22 and 23. Headquarters will be at t Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold tic City, Oct. 23 to 28.

AMERICAN SOCIETY FOR STEEL TREATI will hold its International Steel Expositi and Convention in the General Moto Bldg., Detroit, Mich., Oct. 2 to 7.

ANNUAL SAFETY CONGRESS OF TH NATIONAL SAFETY COUNCIL will be held Detroit, Mich., Aug. 28-Sept. 2.

NATIONAL EXPOSITION OF CHEMICAL I DUSTRIES (EIGHTH) will be held in Ne York Sept. 11-16.

NATIONAL EXPOSITION OF POWER A MECHANICAL ENGINEERING will be held the Grand Central Palace Dec. 7-13, wi the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY has d continued meetings for the summer, b will resume them in October.

THE SOCIETY OF INDUSTRIAL ENGINEE will hold its next national convention a exhibitions of labor-saving equipment the Hotel McAlpin, New York, October

As They Do It In Scotland

THE GLASGOW meeting of the Society of Chemical Industry, which is reported elsewhere in our columns, indicates that they are keeping chemistry alive in Great Britain. Compared with the meetings of the American Chemical Society its purpose is clearly more social and less devoted to the presentation of papers. Thus, in a meeting which lasted a week, the only papers were the address of the president, the Messel medal address, one on the calibration of storage tanks, one on the viscosity of cellulose in cuprammonium hydroxide, and four papers under the general heading of evaporation and distillation given under the auspices of the chemical engineering group. The fact is, the purpose of the meeting is not for members to read papers to one another; it is rather to see things and to talk informally.

Indeed, at the meetings of the chemical engineering group, which is a very lively section of the society, the authors of the papers do not read them. They are printed in full and distributed. The authors talk about their papers and answer questions which are launched from the floor in great profusion. The chairman is selected with great care as one familiar with the subject under discussion and acquainted with those who have addressed themselves to its problems. There were three members of the American Section of the Society (i.e., the Section in the United States, and not including the five Canadian branches), Messrs. J. V. N. DORR, HENRY WIGGLESWORTH and our consulting editor, ELLWOOD HENDRICK. We gather that from the tales these gentlemen are likely to bring home other cis-Atlantic members will make a point of attending British meetings in the future.

The welcome provided by the City of Glasgow was made an event of such distinction and grace as to be long remembered by those who were present.

Success at $2.50 Per Year

"BECOME an executive! Don't envy the man behind the mahogany desk, get there yourself."

We could go on quoting advertisements in almost any magazine in the United States, the very number of which is evidence of the success of the ventures which they are promoting. Some magazines devote themselves almost exclusively to stories as to how JOHN SMITH, hardware manufacturer, or furniture dealer, or city editor, became a success—or how he thinks he became a success. There is danger in all of this, danger that men will believe success is due to some trick system or catch phrase. The influence of these things upon the community is unbalancing. It leads inevitably to a superficial view of success. It conceals the cardinal fact that success in any field is the result of work and intelligent study.

How many times have you heard a young man say, "I believe that I have executive ability, and I want to become an executive. I don't want to waste my time in a minor capacity." Right here is the real tragedy of this philosophy of success. JOHN SMITH, carpet manufacturer, may like to believe that his success was due to the advice given him by a friend of his young manhood, who said "Never weaken," or some equally inspiring thing. But JOHN SMITH'S success has behind it 30 years of work, of intelligent concentration, of detail, and those things are not emphasized or even mentioned. All this tempts the younger generation to believe that if only someone says to them "Never weaken," then they are fated for certain success at an early age.

What young Americans need, and this applies to young technical men as much as to any other group, is a task master and whip. Perhaps someone can suggest another antidote for the insidious poison that success is to be obtained by cutting magazine advertisement coupons, or by subscribing to a course of reading, or by reading a particular magazine, or by following a given catch phrase. The task master and the whip have produced results in the past. Something must make men realize that intelligent study and hard work are the sure roads to success and make them abandon their gods of clay which produce nothing but swollen vanity and baseless self-confidence.

The Portland Cement Industry And Its Association

TRADE associations have been very much in the limelight recently, partly because the Attorney-General of the United States has suspected them of violating the Sherman act; partly because Mr. HOOVER has done his best to find out from the Attorney-General what a trade association should do and what it should not do; and partly because of the vast and increasing number of trade associations in existence at the present time in the United States. The Portland Cement Association is one of the largest in the country and the methods by which it works as well as the aims toward which it is working are interesting. In this issue we are publishing an account of the association and its work. The article is instructive from another point of view in that it represents all that is now safe for a trade association to undertake. You can be assured that with the federal investigation searchlight turned on trade associations none of them is going to undertake anything that is not perfectly conservative. Particularly is this true of the Cement Association, whose members are under federal indictment at the present time for conspiracy on price fixing.

From the chemical engineering point of view there are other phases of this question of portland cement

which are disquieting. The Portland Cement Association has sponsored and carried out a good piece of work in standardizing the specifications of portland cement. It, however, has not standardized portland cement. Some grades are very much better than others. All of them pass the requirements of the standard specifications, but some of them just barely pass it, and others pass it by a very wide margin. It is therefore inevitable that within a short time there will be a grading of cement. The cement industry does not welcome this, as it will complicate sales and manufacturing, but there is a strong demand for it by many prominent civil engineers. Some of the more progressive cement manufacturers favor it, realizing that their own particular product is far better than the average on the market.

Again, there is another phase of the question which is closely associated with the grading of cement. We have reference to the bettering of portland cement as a product. Very little work is being done on that at the present time. The Portland Cement Association is confining itself to the education of the public in the use of its present product and claims that there is no use in manufacturing a better grade of cement until the public knows how to use the present grade. There is something in this, of course, but no industry can be regarded as healthy which disregards completely the work of improving its product. What is the portland cement industry going to do about it?

Finally, there is a strong disbelief on the part of many that the Cement Association is teaching the public how to make better concrete. Invariably every improvement in concrete making which is announced indicates the desirability of using more cement. After a certain time this becomes monotonous and then suspicious. If there be truth in this belief, then the cement industry would better beware. You can't fool all of the people all of the time. Woe betide the person or the industry that tries it. Who's for the defense?

Chemical Industry Supports the Foundation

DEVELOPMENTS during the past week in the proceedings of the government against the Chemical Foundation were marked by a very noticeable rally on the part of the chemical industry to the support of the Chemical Foundation. The Synthetic Organic Chemical Manufacturers' Association called on the President and expressed confidence in the Foundation and its management and argued against any interference on the part of the government on account of the adverse effect it would have on the development of our organic chemical industry. About the same time the National Association of Finishers of Cotton Fabrics adopted resolutions protesting against any action that might jeopardize the success of the organic chemical industry in this country and aid in re-establishing a German monopoly. Subsequently the American Chemical Society appointed a strong committee and requested an interview with the President, which, at the time of writing, had not been granted. It is to be hoped that the President will find time in the midst of the burdens laid upon him by the railroad and coal strikes to listen to the American Chemical Society's committee. In many respects it would speak more disinterestedly than our chemical trade associations and would add professional weight to the representations that have already been made. This committee comprises men of unquestioned eminence in the profession and integrity as citizens, and they could speak with authority and be heard with respect.

With this evidence of the unstinted support of the industry it may not be out of place to suggest that Mr. GARVAN be less active in speaking in his own behalf. His course thus far is not above criticism, and has added no weight to his cause. His letter to the President was in bad taste. His indulgence in flag-waving and eagle-screaming pyrotechnics accomplished specifically what he, and we, desired to avoid—namely, "to becloud the vital issue." The fireworks have been overplayed. Our distinct preference is to support the cause of the Chemical Foundation and consequently we dislike to see that cause jeopardized by indulgence in discourteous bombast. Let the Attorney-General do the talking and play his politics. Let the Chemical Foundation and the chemical industry acquit themselves in a dignified way under circumstances that are admittedly serious and trying.

Erratic Market In Building Construction

PRESENT times are marked by a deal of preaching on stabilization of markets and study of "the business cycle" and a remarkable disregard, in actual practice, of the principles preached. Those who have studied the great upward and downward swings that business in the United States has exhibited have been urging that men heed the obvious lesson of the business cycle and endeavor to make their expenditures when they can get the most for their money and curtail their expenditures when the dollar will not go so far; but the average man seems to study the indices of business conditions with precisely the opposite ambition. When he sees business is good he wants to "take hold" and *vice versa*.

The great ups and downs in business activity are not necessary. At least, neither those who have studied the matter most carefully nor those who have not studied it at all show any disposition to claim that they are necessary. The business cycle has no friends, yet it continues thriving.

There has been talk of "stabilizing" the coal market, by developing a plan whereby people would realize in summer that they will desire to burn coal next winter. The idea is feasible enough, for coal can be stored. One can carry a stock of greater or less amount, anything above zero. One cannot go short of coal, or consume more than he has. In building construction there is more leeway. One can build ahead of time or he can wait beyond the most desirable time, from the standpoint of convenience, and thus there is really more latitude in building than there is in the consumption of materials that are needed for manufacturing operations.

Despite this obvious fact, one observes that there is a more erratic market in building construction than there is in most commodity markets. We have spells when there is scarcely any construction and other spells, like the present, when building construction is extremely heavy. This is particularly true of dwelling-house construction. The only kind of building that has shown a strong tendency to take advantage of the business cycle is office building. It is the estimate of men well posted that about 85 per cent of all the skyscraper office buildings in the United States have been erected, or more accurately speaking, contracted for in times of business depression.

The present wave of dwelling-house construction

which is felt in nearly all sections of the country, is probably due to a great many men having come to the conclusion at the same time that "now is the time to build." The individual opinion probably was that others were going to build later, hence everyone tried to beat everyone else. Had it been possible to get a house actually built at the cost and within the time that were estimated last autumn or winter the builders might have realized their individual ambitions, but it is one thing to make an estimate and another thing to obtain the expected results. On account of the extreme activity many houses are costing more to build and are slower in construction than was estimated.

During the war it was commonly predicted that afterward there would be a period of several years of active building construction. The casual observer might think that now we have just entered upon the period and expect it to continue for several years at the present pace. The probability, however, is that this particular kind of activity will decrease as rapidly as it increased.

Ido Versus The Great Inertia

IN OUR columns this week we print a letter from one of our readers who has been interested in the Esperanto-Ido controversy. In the universal language idea he sees a great boon to technical men in general and he outlines a very logical program for the introduction of one of these universal languages into engineering work. The interest which has been aroused in this subject rather necessitates our taking a definite position in the matter.

Somewhat reprehensibly perhaps, our attitude toward a universal language has been *laissez faire*. We find ourselves asking the somewhat colloquial question—What's the idea? We find also that a vast majority of our contemporaries ask the same question and adopt the same attitude. That is the most serious drawback to the introduction of a universal language. Most people are not particularly interested in the subject and do not see the benefits that might accrue. The general attitude might be called a cold neutrality, which is unfortunate for any movement. An active opposition is better than neutrality, for it always gets the idea talked about pro and con, and excites an interest in the subject.

The general proposition of studying Ido or Esperanto for two or three months and then being able to read any scientific article in the world is rather tempting, and for the accomplished fact we can feel nothing but enthusiasm. Three or four years of French and German, to say nothing of Italian and Russian, rather makes the two or three months spent on Ido seem like a godsend, but alas, scientific literature at the present time is not printed in Ido and even if we spent two or three months learning it, it wouldn't do us a great deal of good. There's the rub. The tremendous difficulty of getting any publisher to print a column of Ido, let alone a whole magazine, would be well nigh insurmountable.

The plight of the metric system in the United States and Great Britain is an object lesson in this matter. Certainly, if ever there was logic in anything, the metric system should be adopted both in the United States and Great Britain, but it has not been adopted in either place and it will be many a long year before it is adopted as the exclusive system of weights and measures. The stone wall of current practice is a pretty difficult thing to surmount and if the metric system fails, how much more completely impossible would it be to introduce a new language. In Germany it is even impossible to avoid the use of an archaic style of printing. If we can't internationalize type, how can we hope to internationalize language?

There are many delightful pastimes and avocations in which we should like to indulge, but we are pressed with more serious business. Hence we shall forego the novelty of printing a column of Ido each week, and must decline to lend the active support of the magazine to the advancement of the cause of an international language. We fear we are part and parcel of the great inertia.

Raising the Standard of Chemical Engineering Education

THE OLDER half of this generation probably remembers the fly-by-night medical school which gave diplomas for a short course and permitted the recipient to use the title of doctor. This species of school and its products are now happily extinct or practically so. The most potent influence in eliminating them was the attitude of the American Medical Association toward medical education. It gave and continues to give its approval to medical courses which measure up to recognized standards of excellence. It did not give its approval to courses presented by institutions which did not live up to these standards. This naturally created a drift of students toward the better class of medical school, which was reinforced by the fact that the members of state licensing boards were members of the American Medical Association and graduates of reputable and approved institutions. Little by little the fly-by-night medical schools vanished.

A somewhat analogous situation exists in chemical engineering. There are schools in this country that turn out so-called chemical engineers inadequately trained, a menace to the profession because they call themselves chemical engineers. In unanimously adopting a program that calls for the approval of schools in chemical engineering which have recognized merits, the American Institute of Chemical Engineers has made a salutary and progressive move toward remedying an evil. Colleges and universities giving courses in chemical engineering undoubtedly will have due respect for the opinion of the American Institute of Chemical Engineers and will receive with courtesy its suggestion as to changes in curriculum. The approval of the Institute will mean much. But its failure to approve will mean more, because it will seriously militate against the popularity of the school in question. Students are quick to recognize that a course is regarded favorably or unfavorably in the profession and will very quickly flock to an approved school. With the possibility of disapproval imminent, the co-operation on the part of college and university authorities is likely to be prompt and enthusiastic. The Institute had loaded the old family shotgun with real ammunition instead of blank cartridges! It is to be congratulated on its courage and foresight.

There is perhaps one word of caution that should be uttered. In educational work a large part of the value received by the student is due to the personality of the professor, and this must be taken strongly into account in evaluating certain courses in any curriculum of chemical engineering. With due regard for the character of the personnel, as well as the nature of the course, the Institute can hardly go too far.

Readers' Views and Comments

To the Editor of Chemical and Metallurgical Engineering

SIR:—I note the good natured controversy in your columns between the proponents of Esperanto and Ido for an International language.

It appears to me that the supporters are trying to use the arguments of each for its being the best *universal* language and trying to make those arguments stick with regard to a limited field of usefulness. Without going into the merits of either as to a general field of usefulness in commerce, finance, politics, traveling, etc., it seems to me that what the engineer is interested in is a language adaptable to his immediate needs, so that in six weeks in college he may read any technical book or table of statistics. This would ultimately eliminate the necessity of two, three, or four years of French, German, etc.

It is my vague impression that for a universal, all-purpose language, the vocabulary should be so arranged that the root words are proportioned in number to the total number of prospective users speaking any language. That is, to be more clear, if the number of prospective users now speaking English is four hundred million or so, and the number of users speaking Arabic is also four hundred million or so, then the number of basic roots taken from the Arabic should be equal to the number taken from the English and so on. So much for all-purpose language. Now, since the Arabic speaking population can never be expected to shine in science or engineering, it would be useless to go to the Arabic for root words in any language intended for use only by technical men. Similarly with the Chinese, Esquimo, Abyssinian, etc., roots.

Hence it appears to me that any language which has its root words—that is, its vocabulary—pretty well rounded off with respect to the different European languages would be ample for all reasonable technical uses. It would seem that both Esperanto and Ido fall in this class, so we need not look further.

The matter of temporary deficiency of vocabulary is pretty easy to remedy since technical terms are to a quite appreciable extent internationalized anyway, numbers of them being coined each year from the Latin or Greek and adopted unchanged, or only slightly so, throughout the technical world. The general vocabularies of both languages are probably already pretty complete so their adaptability to expression of thought may be considered to be ample.

There remains only the question of the introduction of the particular language chosen. Should this language never come into general public use but remain forever a technical language, there would be only a small loss to each individual as I am told that any of them can be very well learned in a few months. Furthermore, it would be no considerable task to introduce one or the other, and receive its benefits soon. A commercial language could come along later.

I would suggest that the various large technical societies hold a convention, choose and recommend whichever seems best fitted for the use of the members speaking that particular native tongue. The next step would be an international convention of technical bodies and government representatives to thresh out the same question for the technical world as a whole. This recommendation would be final but would still be only recommendation. The third step would be a tryout. Such bodies as the Bureau of Standards, the Smithsonian Institute, the Naval Observatory, and like bodies in other countries would then publish their statistical works in the form of an interlinear translation, that is, the works would be published as at present but with the addition that after the explanation in the native tongue, the same explanation in, say Esperanto, would follow. This would incur very small expense as in such works as the Smithsonian Tables, the numbers are the main thing and the explanations generally occupy only a few lines per page. If British, French, and German organizations followed suit, this would be a very efficient and economical tryout.

Should this be favorable, the fourth step would be more daring. Some magazine, for instance this one, could publish for a couple of years a double issue as is now published by the magazine *Sugar* which has a Spanish edition bound in with the English edition. This would be more expensive as a tryout, but if still successful we are off, and are at once receiving the benefits of the new international technical language. Other magazines, and even book publishers would shortly fall into line. Further, if a success, this very success would stimulate the use of this or another similar language in commerce, and other foreign intercourse.

I hope my ideas will be of interest to you.

Manufacture of Hydrogen Peroxide

To the Editor of Chemical & Metallurgical Engineering

SIR:—More than forty years ago the writer was chemist and manager for Charles Marchand, an ingenious Frenchman who first made H_2O_2 a commercial success. In that capacity I worked out a method for the manufacture of BaO_2, under which many tons of this material were produced. While working in this line the late Professor Joy of Columbia drew my attention to the reaction with CO_2 and I made a number of experiments, producing considerable quantities of hydrogen peroxide at various times without observing that the product was more unstable than that made by Marchand with Thenard's process. But later I went into the experiments much more intensively and completely and was therefore much surprised at the article in your issue of June 14, 1922,[1] re-describing the same process, for this must have been tried by many besides myself.

When I repeated my experiments, now many years ago, the process was carried on in a pressure vessel kept in motion continually and at a pressure of about 100 lb. to the inch. From the first no attempt was made to work the method in unlined vessels and the wrought-iron pressure tank was lined with porcelain.

[1] "Hydrogen Peroxide—A Novel Process for Its Manufacture," by H. A. Doerner, *Chem. & Met. Eng.*, vol. 26, No. 4, pp. 1111-2 June 14, 1922.

bricks of the same quality as used in cylinder mills, but of smaller size. These bricks were cemented together with caustic baryta, which sets into a very hard binder, apparently expanding slightly, like plaster of paris. Many difficulties were encountered and overcome, but there was one not mentioned in that article, which resulted from the production of barium percarbonate and proved more troublesome than all the rest. Under pressure a sort of bi-percarbonate seems to form, probably of the composition BaC_2O_6. This is very unstable, somewhat soluble, at least in the carbonic-acid solution and when removed by H_2SO_4 it is prone to cause a loss of oxygen which should have been held in the peroxide.

The product was never handled commercially, for the high price of CO_2 at that time made it impracticable. Besides, I became convinced that it was one of those things which must be handled on a large scale to be economical and enable the use of comparatively unskilled labor. But the process has undoubted possibilities, and what I did before abandoning the thing convinced me that there were no obstacles that were not easily surmountable. Unfortunately, my notes are not accessible, so that I rely upon memory and cannot go into details, but the process as described in your article is practically a replica, on a rather larger scale, of what was done years ago. H. B. GOETSCHIUS.

Should Engineers Be Licensed?

To the Editor of Chemical & Metallurgical Engineering

SIR:—It is evident from an editorial in the July 5th issue of *Chemical & Metallurgical Engineering* that the laws passed in several states providing for the licensing of all engineers who wish to engage in the practice of professional engineering do not meet with your approval. You point out several possible faults in the scheme.

The editorial states that, whether he likes it or not, the engineer finds himself restricted or hampered by incompetent legislation. I wish to point out that no qualified engineer is restricted or hampered by the New York law in the performance of any professional work that he could with honesty and from an ethical standpoint hope to perform.

You "gravely question whether any good can come of licensing engineers whose work requires the exercise of initiative, ingenuity, judgment or the creative faculties." Let us consider the question of judgment. The lives of all depend on the judgment of engineers and, under a licensing law properly enforced, the risks which we must run will be lessened, for an engineer will never make more than one mistake in judgment which adversely affects public safety; and his disbarment after failure will be an impressive lesson to others who might commit the same errors of judgment. You would confine the license to only such engineers as are responsible for public works. I say that the chemical engineer responsible for a plant liable to explosions or other dangerous accidents may, by his errors in judgment, jeopardize the public safety fully as much as could a bridge designer responsible for a highway bridge. The license law must apply to all engineers on a basis of full equality.

Your editorial goes on to state that licensing of physicians has not worked miracles with the medical profession. No, nor can licensing work miracles with engineering. Truly, we shall choose our engineers as we do our physicians—for proved ability. But licensing of physicians helps enormously to keep the shysters out of the medical profession and we can expect with confidence that in time the license will do as much for engineering. The license certificate cannot, as you point out, make a good engineer out of a poor one and, in the wildest flights of fancy, no one connected with the passage of licensing laws ever expected that is could. But it does not prevent the totally unqualified man from representing himself to a more or less gullible public in the guise of an expert—an occurrence which is not rare, as those who were stung in the "efficiency" engineer fake of some ten years ago will testify in choice language and with much feeling.

The last objection raised by the editorial is that the license certificate does not differentiate between types of engineering practice. To do so would be really to hamper the engineer. He should have the latitude to perform as large a service as he is able to compass. And it is certainly up to the individual engineer to run no risk of losing his license by trying to do work for which his experience and training do not qualify him. Under the law we have the same safeguards that we formerly had against such malpractice with added protection due to each engineer's anxiety so to conduct himself that his license cannot be revoked.

If you will study the law with care you will find that, at least in so far as the New York law is concerned, the fears evoked in your editorial are all chimeras. Prior to the law's passage, the only real opposition it had came from corporations and their hired engineers who vainly hoped, by maintaining the engineer in a position of public disregard, to continue the then situation—when brains could be hired by the unscrupulous for nothing a week. It would give me cause for great amazement and regret to see *Chem. & Met.* definitely line up in such discredited company.

Electric-Furnace Production of Phosphoric Acid

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your report of the Niagara Falls meeting of the American Institute of Chemical Engineers, there is one matter to which I should like to call your attention.

Referring to the discussion by W. H. Waggaman on the production of phosphoric acid, there is not a clear distinction between the furnace using fuel as a source of heat and the electric furnace. The passage in question is on page 13 of your issue for July 5.

I wish to clarify reference to the mention of a plant "designed by one of the men formerly with the Bureau of Soils." This plant is not in any sense connected with the experimental work of Mr. Waggaman on fuel-fired furnaces and is not in an "investigation stage." On the contrary, it is a full size plant, and regularly producing considerable quantity of phosphoric acid. Further, the reference to the short runs and comparative estimates on the cost of producing phosphoric acid refers to the work of Mr. Waggaman and not the acid work at Anniston.

So far as is known to the writer, the basis of comparison of cost of production of phosphoric acid is the result of Mr. Waggaman's short runs and estimated cost on electric furnaces as published by the writer while connected with the Bureau of Soils.

Automatic Equipment and Chemical Control

By Graham L. Montgomery

The Beverage Industry Based on Automatic Equipment for Competitive Purposes and Chemical Control for Purity—Description of the Beech-Nut Packing Co.'s Ginger Ale Plant at Canajoharie, N. Y., an Illustration of the Combination of These Two Important Methods

TO KEEP a continuous, active market for a beverage, the manufacturer must meet three main essential requirements. The price must be such that the product can hold its place in a highly competitive market. The flavor, quality and purity of the beverage must be such as to create a continuous demand among consumers. The beverage must be so made as to be acceptable under all state and federal pure food and health laws.

On the matter of price, the raw materials which enter into the manufacture of beverages are only a slight fraction of the cost of the finished and bottled product. Also, these materials present no particular chance of advantage, as the price fluctuations in the long run will equalize their cost for all manufacturers.

The possibilities of savings lie then in the manufacturing costs. This fact was early recognized by the industry at large and as a consequence, we find that automatic machinery and handling devices are employed by these manufacturers wherever there is any possibility of effective use of this equipment.

The matter of flavor, quality and purity necessary to create and maintain a popular demand is so tightly bound to the matter of purity to comply with the law that these two essentials must be considered as under one head. To accomplish these results it is necessary to establish and maintain a strict chemical and bacteriological check on all stages of the manufacture and bottling of the beverage.

Some Essentials of Beverage Manufacture

Before passing to the specific example of modern beverage manufacturing practice which forms the major portion of this article, there are certain essentials of manufacture which those interested in this industry should bear in mind.

In the first place, all the raw materials used must be pure and of good quality. Water forms the greater part of all non-alcoholic drinks and particular care must be exercised to obtain a pure water of good flavor with the proper degree of hardness. The other materials—those used to make up the flavoring of the beverage—should be absolutely unadulterated, fresh and of good flavor. If these essentials of quality are observed in the selection of the water and other materials it becomes possible to fix on a blend of pleasing flavor and to maintain this constant at all times.

Most of the popular beverages are charged with CO_2 or carbonated. If any bottles of such a beverage reach the consumer in a flat condition, *i.e.*, with the CO_2 discharged, there is much complaint and the sales of that particular beverage are likely to be materially lessened. Hence the successful manufacturer goes to some little trouble and expense to see that the bottles of his beverage are uniformly charged and are sealed tight.

Among items which will not be stressed here but which have a direct influence on the manufacturer's success might be mentioned the control of a supply of bottles and packing-cases. It is evident with but little consideration that any advantages a manufacturer can obtain along this line will be of direct advantage in enabling him to keep costs at a minimum.

The Beech-Nut Packing Company

The Beech-Nut Packing Co., manufacturers of various food products, has been located at Canajoharie, N. Y., for many years. When they contemplated the addition of non-alcohol beverages such as ginger-ale and root-beer to their products, this location was found to be fully as good as could be found elsewhere for the purpose.

As stated above, the largest part of these "soft" drinks consists of water. A few miles north of the town of Canajoharie, in the foothills of the Adirondack Mountains, are located the Sprite springs, yielding a large supply of exceptionally pure water with low mineral content. These springs were acquired and now form the basis of the manufacture of beverages at Canajoharie. The water has sufficient head to flow naturally to the plant site. The watershed of the springs has been fenced and is well guarded against pollution.

Method of Purifying the Water

On first entering the plant the water passes through a meter. Immediately after the meter are four Bowden filters, piped in parallel so that one or two units can be out of use for cleaning or refilling. The water in passing through these filters encounters first a layer of coarse quartz, then a layer of fine quartz, and finally a layer of bone coal. This first filtering serves to remove all coarse suspended matter and the bone coal absorbs any cloudiness or odors which may be in the water.

After passing the Bowden filters, the water goes through one of four International filters. These are arranged in parallel in a similar manner to the first filters. The filtering medium consists of a thick, dense filter paper, protected on the inlet side by a cover of loosely woven cotton cloth which serves to intercept any of the bone coal which might be carried over from the first filter. The International and Bowden filters remove practically all material from the water which can possibly be removed by filtering.

Beyond the filters, the water flows through the sterilizers. These are of the ultra-violet ray type and consist of two concrete tanks, either one of which can take the whole load of the plant. In each tank are two weirs with openings about 4 inches long and $\frac{5}{8}$-in. deep, through which the water flows slowly, passing over the tube containing the arc which produces the ultra-violet ray.

The accompanying photograph of the water purification department shows the Bowden filters on the right, the International filters in the center and the sterilizer on the left.

After passing through the sterilizer, the water flows by gravity to the floor below. There it is divided into three streams, the largest to be carbonated, a second

to form the solvent for mixing the flavoring syrup and the remainder to be used for washing and rinsing bottles.

How the Water Is Carbonated

The bottling process used by the Beech-Nut Company is that known as the low-pressure process. This process depends on the fact that water at a low temperature will absorb and retain a far greater amount of CO_2 than at ordinary temperatures. For this reason the water which is to be carbonated is first passed over a direct expansion cooling coil supplied with a cooling medium from a 75-ton compression refrigerating set. This cools the water to an average temperature of 34 deg. F., a check being maintained on this temperature by means of a Foxboro recording thermometer.

After passing the cooling coil, the water enters the carbonators. These five machines, manufactured by the Liquid Carbonic Co., operate automatically, being governed through liquid level and counterweight so that when the carbonated water in the base of the machine is drawn off below a fixed low level, the machine starts to operate and continues to do so until the carbonated water level reaches a fixed high level. There are five of these machines operating in parallel on the pipe line between the cooling coil and the filling machines on the next floor below.

The operation of the carbonating machines, shown in the accompanying illustration, is as follows. The water is pumped in at the top of the column shown on the forward part of the machine by a geared pump, located at the rear of the machine. As it falls down through this column it is broken up into a fine spray. This spray comes into contact with CO_2 gas coming upward through the column. The CO_2 is introduced at the bottom of the machine where the main casting forms a reservoir for carbonated water. The gas bubbles up through this agitated water maintaining the saturated condition which the water acquired in the column. The CO_2 is received in pressure cylinders at 750 lb. pressure and is fed to the carbonator, through a reducing valve, at a pressure of 75 lb. A Foxboro recording pressure gage is installed on this pipe line.

As it is required in the bottling process taking place on the floor below, the charged water is drawn off from the carbonators through Berkefeld filters, shown on the left of the same illustration which shows these carbonators. After passing through these filters the water tests negative under all bacteriological tests.

The water to be used in syrup making flows as needed from the sterilizers to the copper heating kettles in which it is heated, together with sugar, to form the simple sugar syrup which is the basis of the flavored syrup used in the various beverages.

The water which is to be used to wash and rinse bottles is delivered by a pump situated on the same floor as the carbonators, the third floor. This pump takes the water from the sterilizers on the fourth floor and delivers it to the soaking and rinsing machines on the second floor at the pressure and in the quantity desired.

Manufacture of Flavoring Extract

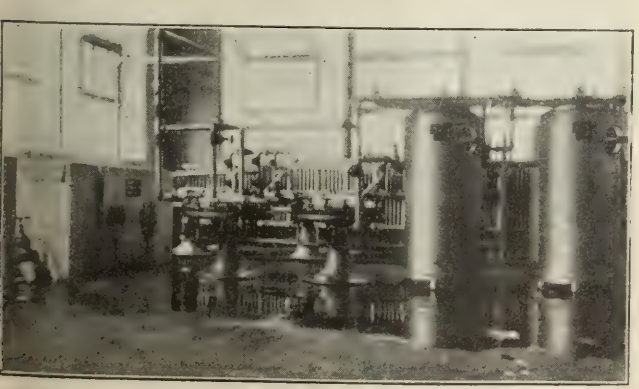
At the Beech-Nut Company's ginger-ale plant, the materials which go to make up the flavoring extract are purchased in as near the raw or original state as possible. It is easier in this way to get pure materials and to control the blend so as to have the flavor exactly the same at all times.

For the purpose of illustrating how the extract is made let us consider that used in flavoring ginger ale. The basis of this flavor is ginger root. Other vegetable products that can be directly extracted are handled in the same way. This root is first pulverized in a Jeffrey pulverizing mill. The pulverized material is then placed in a percolator. The percolators used are of heavily tinned sheet metal and in general design are like a large funnel. These percolators, removably suspended from the room ceiling by hooks, are provided with covers and with valves at their lower or discharge ends. The material to be extracted, about 150 lb. at a time, is placed in a cloth bag and suspended in the percolator. Pure grain alcohol is then allowed to trickle down through the pulverized mass, thus extracting the flavor of the ginger or other material.

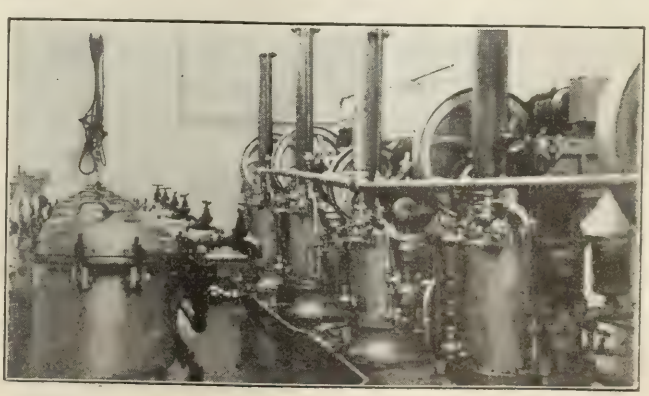
The crude extract which comes from the percolators contains a small amount of tarry material from the ginger roots. To get rid of this, the extract is placed in a Pfaudler glass-lined agitating tank with distilled water and thoroughly washed.

A certain amount of alcohol remains in the woody mass of waste removed from the percolator after the extracting is finished. To recover this, the waste is placed in a small Tolhurst centrifugal extractor. This machine recovers all but a small proportion of the alcohol, which can be purified by distillation and reused.

The essential oils of lime, lemon and orange are used in the flavoring of many soft drinks including ginger-ale. These oils are purchased in the crude state. In this condition they contain terpene and must be refined by extracting the terpene with alcohol. By doing this refining at the plant, it is possible to keep the strength, quality and purity of the refined oil always the same. These factors would not be so easy to control if the oils were purchased in the refined state.



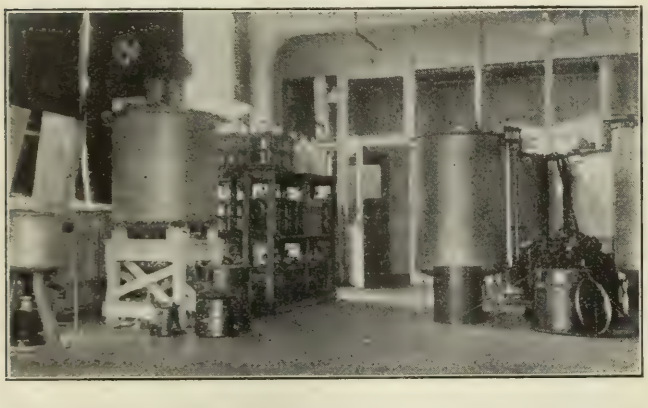
WATER PURIFICATION APPARATUS



CARBONATORS AND BERKEFELD FILTERS

The extract and the essential oil are both carefully filtered through paper. They are then placed in one of the storage tanks in the proper proportion to produce the desired flavor and allowed to age, which improves the blend. Handling of the extracts, of the essential oils and of the blend of the two is accomplished by means of the portable centrifugal pumping set and the copper cans shown in the accompanying photograph.

This photograph shows on the left the Tolhurst centrifugal extractor, next the Pfaudler glass-lined agitating tank; in the center a stack of the bottles used for essential oil containers and on the right, the six storage tanks and the portable pump. The storage tanks are Pfaudler glass-lined tanks with covers lined with block tin. All are provided with gage glasses to show the depth of the liquid contained. The two shown in the rear are of 600 gal. capacity each for the storage



of the blend. In front of these on the left are two of 200 gal. capacity for distilled water. On the right, only partially shown, are two 200 gal. tanks for storage of the pure grain alcohol.

How the Flavoring Syrup Is Compounded

In a previous paragraph, notice was taken of the compounding of the simple sugar syrup of sterilized water and cane sugar in a heating kettle. Then this mixture is pumped to the mixing department on the fourth floor adjacent to the water purification system. In this department are four 350-gal. Pfaudler glass-lined tanks, a small pump and a Sweetland filter. To a measured quantity of this syrup the proper proportions of the blend of citric acid crystals, and of caramel or burnt sugar coloring are added. Here is performed the operation known as polishing the syrup. Two of the tanks are used for unpolished syrup and two for polished or filtered syrup. By means of the pump the syrup is forced from one set of tanks to the other through the filter. This leaves the syrup clear and brilliant and thoroughly mixed.

Syrup Storage Department

To keep the flavoring syrup until used it is necessary to store it in a cool place. For this reason this department is included within the same insulated walls on the third floor which inclose the sterilized water cooling coil and the carbonating or charging department. Within this space is a room maintained at a temperature of 40 deg. F. by cooling coils and containing four 600-gal. Pfaudler glass-lined tanks for syrup storage.

These tanks are provided with gage glasses and have block-tin-lined covers. All the piping through which the syrup or carbonated water must pass is block tin lined. A Foxboro recording thermometer is installed in the storage room to keep a check on the temperature.

Where the Automatic Equipment Is Used

The preparation of the carbonated water and of the syrup has been described above. These two elements are mixed in the proper proportion to form the completed ginger ale in the bottle at the time of filling.

It will be noticed in the descriptions of processes outlined above that most of the material is handled by pumps or by gravity flow in pipes. The bulk materials to be handled—sugar, ginger root, essential oils, etc.—are very small compared to the amount of liquids. The carbonating equipment is automatic. In the other processes there is little possibility of finding better equipment than that described. Only from four to five men are needed throughout this whole series of operations.

But when we come to the work of placing the ginger ale in the bottles, we find a situation in which the use of any hand labor would be extremely costly. For this reason automatic machines were long ago designed and are now generally employed in this work.

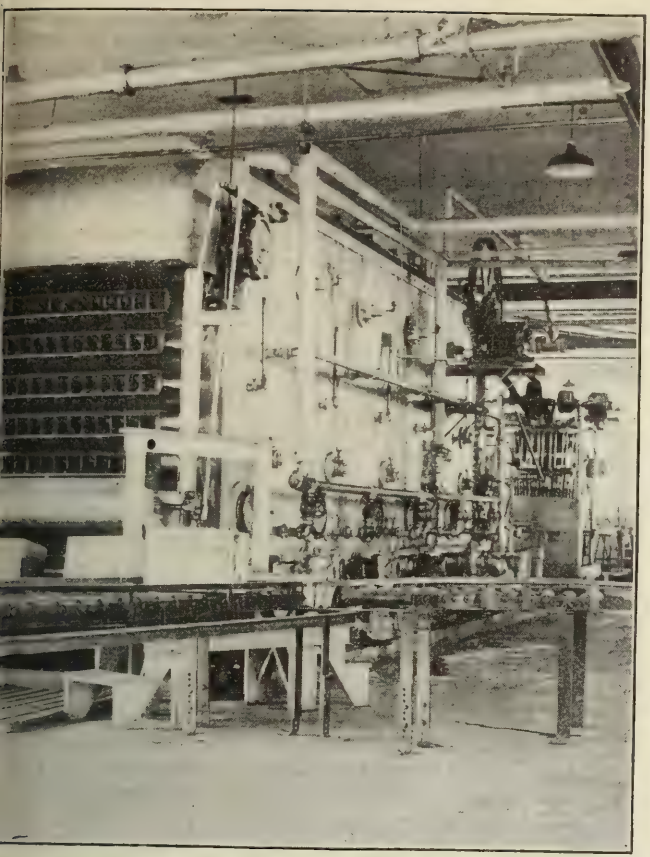
Division Between Manufacturing and Handling of Finished Product

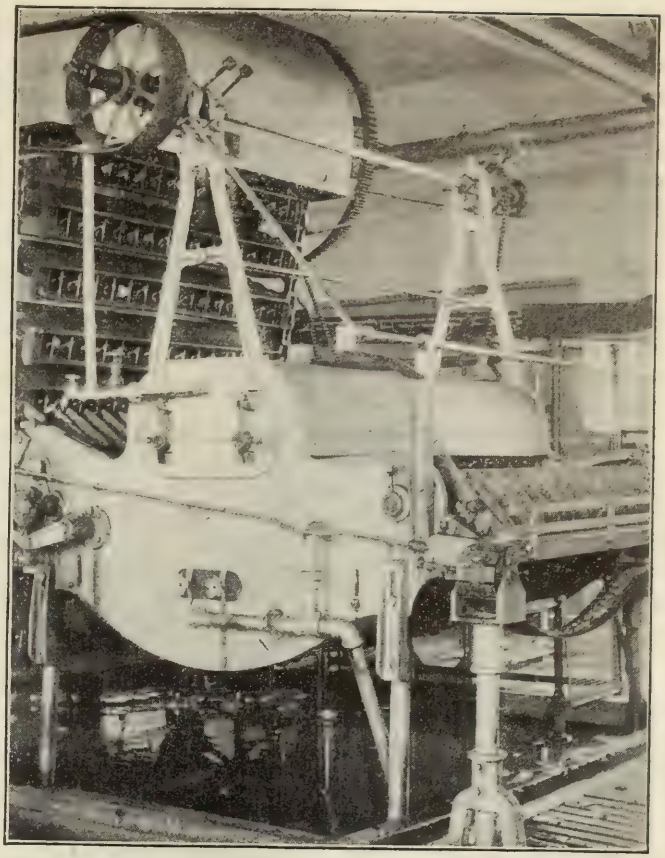
The work of filling the bottles would be classed entirely as handling of finished products except that the mixing of the carbonated water and the syrup takes place in the bottle. For this reason the automatic equipment for handling the bottles and filling and labelling them will be described in this article. The handling equipment used other than that in connection with the automatic machines here described will be the subject of an article entitled "Handling the Finished Products of Industry—IV" to appear in *Chemical & Metallurgical Engineering* for August 2, 1922.

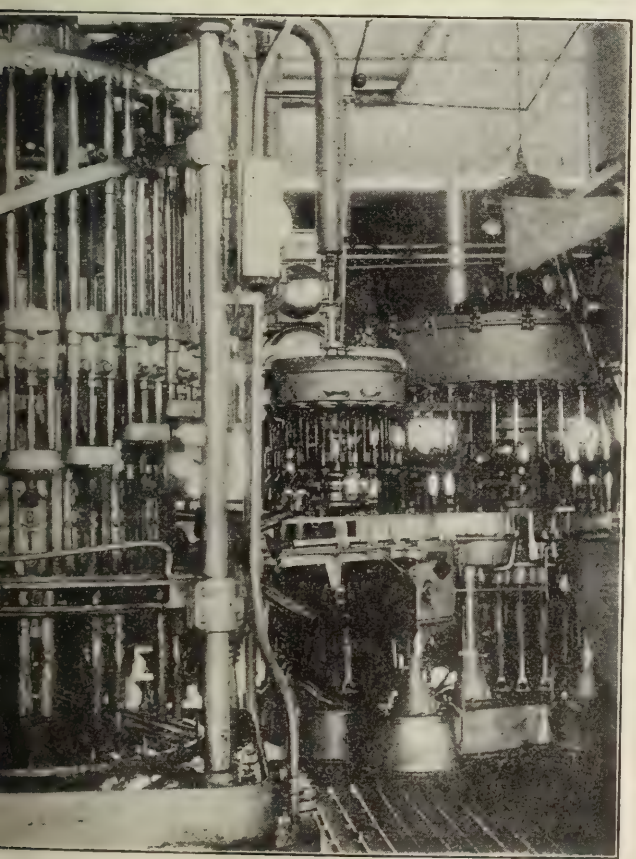
Work Done on Bottles Prior to Filling

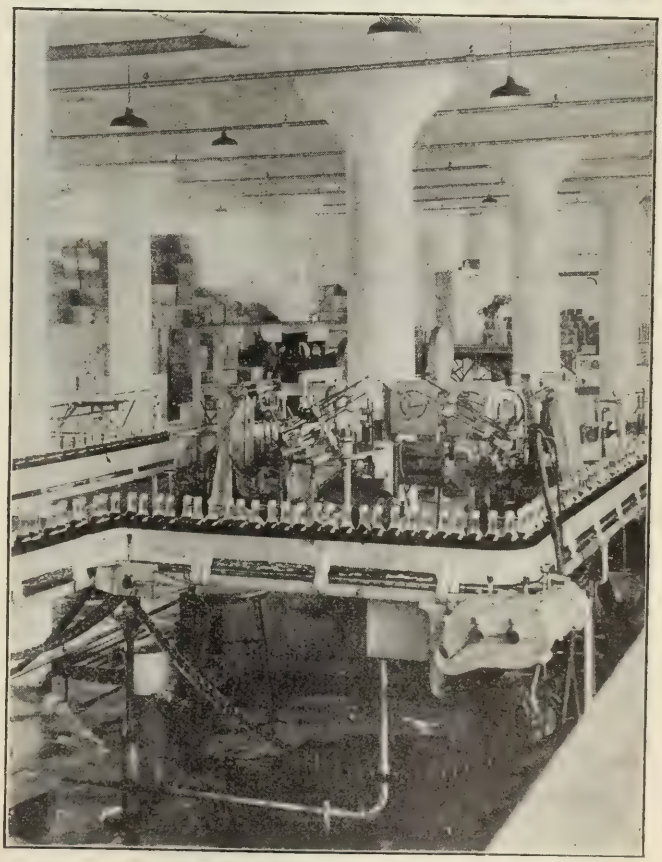
All bottles received at the plant must be thoroughly cleansed before they are filled, whether they are new bottles or bottles returned from dealers. The first operation of this cleansing is performed in the soaker manufactured by Barry-Wehmiller and shown in the accompanying photograph. As can be seen in the picture, the machine consists of five large tanks through which the bottles are carried, 15 abreast, held in the compartments of the chain. The first three tanks are filled with a hot caustic soda solution and the last two are filled with warm sterilized water. The chain makes one upward pass and one downward pass through each tank. Thirty minutes are consumed in passing through the soaker. The soaker and filling equipment are on second floor of the plant, so that water and other liquids are fed by gravity.

The bottles are thoroughly washed in the soaker but any labels which were on returned bottles might still remain on them. So after leaving the soaker the bottles are discharged from the chain compartments, automatically, and go through the brushing machine, also manufactured by Barry-Wehmiller. Channels on a incline receive the bottles as discharged and serve to keep them separate and equally spaced. The bottles slide down these channels under the brushes which rotate on horizontal axes perpendicular to the travel of the bottles. At the same time, the bottles are caused









UPPER LEFT—SOAKER WITH RINSER BEYOND
LOWER LEFT—RINSER AND FILLING HEADS

UPPER RIGHT—BRUSH AT REAR OF SOAKER
LOWER RIGHT—LABELLER AND BOTTLE CHAIN

to rotate on their axes. In this way any labels or other things adhering to the outside of the bottles are brushed off.

After having passed the soaker and brush, it is necessary that the bottles be thoroughly rinsed to remove any possible traces of caustic soda. This rinsing is done with an Arrow Bottlers Co. machine of the rotary type which is shown on the left side of the photograph showing the filling heads.

As the bottles leave the brushing machine they are delivered in an upright position to a single-chain conveyor having flat plates attached on the upper side of its links for the bottles to stand on. This conveyor delivers the bottles directly to the rinser. They enter the top ring of this machine first and as they are carried around they are first partly filled with warm water and then the interior is subjected to a thorough brushing with a high-speed rotating rubber butterfly brush. They are then transferred to the bottom ring of the rinser, being turned at this point so that the neck is down. As they travel around this lower ring the inside is rinsed by a jet of water. The water used by this machine all comes from the sterilizer.

Filling the Bottles

As the bottles leave the rinser they are delivered to a chain conveyor similar to that described above. This conveyor moves them to the first filling machine, called the "syruper," a rotary filling machine manufactured by the Liquid Carbonic Co. As the bottles are taken on this machine and caused to travel around its ring, a regulated amount of the syrup, the compounding of which was described above, is placed in each bottle.

This "syruper" delivers the bottles, over another short single chain conveyor, to the filling machine known as the "filling head," also made by the Liquid Carbonic Co. This machine is similar in construction and operation to the "syruper" except that it is specially designed for use with charged water. As the bottle goes onto the machines' ring, a funnel shaped head is thrust down over the bottle neck. This head makes a gas tight joint around the neck, and the pressure is then built up to 20 lb. before any of the charged water is allowed to enter the bottle. Thus it will be seen that if a bottle is cracked or for some other reason the pressure cannot be built up, no charged water is introduced. The operator picks out these bottles which have only the syrup in them and discards them.

If the bottle will stand the 20-lb. pressure, the valve, on the end of a tube which is projected into the bottle to a point near its bottom, opens and the bottle is gently filled with the cold charged water from the carbonating machines on the floor above. By introducing the charged water in this way it is intimately mixed with the syrup without undue foaming. As both the syrup and the charged water are at a temperature close to the freezing point, there is no undue escape of carbon-dioxide in the short period during which the bottles pass from the "filling head" to the crowning machine.

Crowning, Testing and Labelling Bottles

Transfer from the "filling head" to the crowning machine—a machine made by the O. and J. Manufacturing Co.—is made by means of another single-chain conveyor. This crowning machine crimps the caps on over the lip at the mouth of the bottle.

As the bottles come out of the crowning machine they are placed by hand upright in galvanized wire baskets holding about two dozen bottles each. These baskets are placed on the slat conveyor which conveys them through the test tank. This test tank is a large tank of water maintained at a temperature from 90 to 100 deg. F. It takes 11 minutes for the conveyor to pass through the tank and during this time the bottles are submerged in the warm water.

If there is any possibility of the CO_2 leaking from the bottles and leaving the beverage flat it will show up while the bottle is submerged in the warm water. For, as the bottle warms up, gas escapes into the air space under the crown and the pressure rapidly builds up to as high a point as it would reach under any normal conditions to which the bottle might be exposed. Any bottles which show a leak are removed from the tank by the workman stationed there and thoroughly inspected. If the fault lies in the crowning the bottle is refilled and recapped. If the leakage is due to other causes the bottle is discarded. The percentage of discards is extremely small provided a good strong quality of bottles has been obtained, showing that the automatic machinery is highly efficient.

As the bottles emerge from the testing tank they are removed from the wire baskets and placed on a single-chain conveyor similar to those already described. This carries them to the labelling machine, made by O. & J. Manufacturing Co. Here the labels are affixed and the bottles delivered to another single-chain conveyor. This last conveyor carries them to the inspection department where girl operatives give the final inspection and place them in the wooden shipping cases, 24 bottles to a case.

There are two complete units of this automatic washing, filling, testing and labelling equipment. Each of these units has a capacity of from 1,600 to 1,700 cases of filled bottles per 9-hour day.

Chemical and Bacteriological Control

Throughout the processes described above, a most complete and exhaustive chemical and bacteriological control is maintained over the materials used. The plant is provided with a large laboratory, extensively equipped so that all types of chemical and bacteriological tests can be conducted.

Chemical tests are made on each item of raw materia which goes to make up the product. These tests are made at regular intervals on the water and bulk products and on each container of the small quantity products. As these materials go through the processes regular tests are made after the completion of each step. In this way the quality and flavor of the produc can be uniformly maintained at the point which ha been determined to best meet the popular taste.

Bacteriological tests are made of the water as i enters the plant, after each step of the processes t which the water is subjected, of the various othe liquids used in the manufacture, of the finished produc and of the bottles, both before and after cleaning. Thes enables the company to be sure that the product leavin their plant has a low bacteria count, that the publi health is safeguarded and that the requirements of th various pure food and health laws are fulfilled.

We find then, in the ginger ale plant of the Beech Nut Packing Co., an almost ideal combination of auto matic equipment and chemical control—a combinatio by means of which manufacturing costs are maintaine at the lowest figure and at the same time quality o product is maintained at the highest level.

The Society of Chemical Industry Meets in Glasgow, July 4 to 11, 1922

An Intimate Glimpse of This Live Organization in Action—This Meeting Was a Notable One in Every Way—Abstracts of the Technical Papers Follow the Account of the Meeting

By Ellwood Hendrick

THIS is the fourth time the Society has met in this city since its organization in 1881 and—"Glasgow knows how." It knows how to do many things, not ne least of which is to operate successfully a municipal- y of a million and a half inhabitants—and nearly all of nem Scotch. This latter fact may indicate the reason why. he street railways are municipally owned and a short ide costs a penny, which is two cents, and a long one our pence. The city makes its own gas and works up ne residues. It produces its own electric current at xceedingly low cost. It has no Tammany Society nor ny Republican County Committee nor any Hearst apers. Its policemen and cab-drivers are said to be ostly Irishmen from over Belfast way. Its climate is nly theoretically mild for on the 4th of July a straw at is more of a curiosity on the streets than an vercoat.

Glasgow's Industrial Power

Glasgow is the site of its University and of its echnical College, which is a branch of the University. is headquarters for many chemical industries and ere are important steel works nearby, at the south. he minerals of the district include iron, coal, shale, ays, zinc, lead and its chemical industries are shale l, tar distillation, alkali and acids, cyanides, ferro- anides, bichromates, iodine, explosives (Nobel Works), ls, paints, fertilizers and a great many more. The ction of the Society is a lively one and its members e people of influence.

An Informed and Admirable Lord Provost

At the opening of the meeting in the council room of e beautiful Engineers and Shipbuilders' Institute on ly 4, each registrant received a handbook of the eeting, handsomely bound in Gordon plaid, a guide to lasgow, another guide to Scotland and copies or ab- racts of all the papers to be presented. At 10 o'clock ne Council, about 24 members being present, met for utine business but left the location of the next annual eeting to be determined later. Dr. E. F. Armstrong ad already been chosen president for the next year. t 10:45 the annual general meeting reaffirmed the ac- on of the council and the Lord Provost of Glasgow elivered a speech of welcome.

Now the Lord Provost fulfils the functions of the ayor of the city, and his broad grasp of the meaning chemical industry, the absence of silly pleasantries om his address, and his earnest participation in the rposes and aims of the meeting made your corre- ondent wish for that kind of a mayor in his home wn.

The president, Dr. Ruttan of Montreal, responded racefully in appreciation of the welcome from the city at gave us, among others, Joseph Black, Charles ennant, Kelvin, Sheldon, Ramsay—all of whom were lasgow men. In his presidential address, Dr. Ruttan ve an extensive and complete history of research in ritish possessions since the outbreak of the war and a very thoughtful study of the available methods of developing the resources of the empire. The stimulus of the meeting in Canada and of the International meeting in New York last year was duly recognized, but his problem had to do with carrying on the development and keeping up the general and public interest in research. His conclusion—and he gave many reasons in support of it—was that a series of colonial and imperial institutes of research be organized somewhat on the line of the Mellon Institute at Pittsburgh, would be the best solution. Out of the inter-relations of such establishments in the various British possessions he believed that great good might come. His information as to the present status of the various Research Institutes of Canada, Australia, New Zealand, South Africa, India, and elsewhere shed additional light on his proposal.

President-elect Armstrong, in the discussion which followed, spoke of the hazard of a possible bureaucratic control of research as his only criticism of the plan. In a considerable number of cases in various countries since the war, the efforts made to organize research have taught him to fear the ill-effects of too much of this good thing.

At 1 o'clock an informal luncheon was held at the Grosvenor restaurant in Gordon Street, Glasgow's leading establishment of its kind. Mr. J. H. Young, chairman of the Glasgow section presided, and he and Dr. Ruttan made short but pleasing addresses. There were about 300 present.

At 3 o'clock the party went out on special street cars to a garden party at the house of Mr. David Parry, a leading alkali manufacturer of Glasgow and president of the Society in 1905-06. He has a beautiful estate and here were marquees and settles and awnings, with all the paraphenalia of a garden party, and a band and Scotch pipers, and the famous Glasgow cakes, and dancers who did the highland fling, and there was sunshine and many beautiful Scotch ladies.

The Reception

At 7:30 o'clock (they have daylight saving time, and at this latitude it hardly grows dark until the clock strikes 11) the Hon. Lord Provost and the magistrates of Glasgow received the members of the Society and ladies with them at the great Municipal Buildings. The Lord Provost and the Magistrates in their robes of office, respectively in purple and black and ermine, and with golden chains and medallions, received each guest with ceremony. Then a procession was formed of their eminences and the president, officers, and a few members of the Society, including the representative of the American Section, who took place on the platform of the great hall. Before them were gathered the members of the society and many distinguished persons, invited by the municipality—a large conclave, all in evening dress, including some gentlemen who wore the kilts of their clans. The Lord Provost spoke of the great value to the city which the application of chemistry had proved, how through the efforts of Mr.

Walmsley great savings had been made in their gas products recovery plants. Dr. Ruttan said the right thing and Mr. Young made a plea for the greater glory of chemistry, after which the dancing began.

But some of us are getting along in years and a trifle stiff in the legs, so that for such that did not dance another entertainment was provided. This was in the council chamber where the Glasgow Select Choir, and organization of 18 mixed voices sang, *a capella*, from 8 until 10. This is a famous body of musicians and they have sung in the United States and Canada as well as all over Great Britain. Now after sitting through the concert, the writer of these lines challenges any reader of them to hear the Glasgow Select Choir sing "The Auld Hoose" without getting a bit thick in the throat or wet in the eye, or "Scots wha' hae" without imagining himself a Scotsman and almost feeling as if he could tear up the whole of Mount Vesuvius if he had a mind to. In addition to all this a bountiful collation was served.

Glasgow wants it understood that it believes in and approves of chemistry and chemists. It knows what they are because it has raised them.

Award of the Messel Medal to Prof. Armstrong

Wednesday the 5th was just as lively a day. It began with the first Messel Memorial lecture by Professor Henry E. Armstrong. The late Dr. Rudolph Messel, who many of our readers will remember as president of the Society during the eigth International Congress of Applied Chemistry at New York in 1912, left £20,000 to the society by his will. The Society resolved to give a medal bearing the name and likeness of the donor to the most distinguished chemist of his time in England as the occasion for doing so may arise. Professor Armstrong was the choice this year and his address bore the title, "Rhapsodies Culled from the Thionic Epos." The speaker's delivery was too rapid and mild in voice for the writer to gather more than random notes from it, but we may say that that was the only evidence of mildness which the speaker displayed in his delivery. Professor Armstrong is as peppery as ever and the substance of his discourse was a plea to get back to chemistry, interspersed with frequent flashes of wit and a crack on the head for everyone who did not agree with him. It will probably be published in the form of a booklet and it will make lively reading.

Two technological papers followed on "A Rapid and Accurate Method for the Calibration of Storage Tanks," by Dr. J. W. McDavid and "The Viscosity of Cellulose in Cuprammonium Hydroxide" by Dr. R. A. Joyner, both of the Noble works. They are abstracted below.

An informal luncheon took place again at 1 o'clock and this time the Principal of the University made a short but fitting and very polished address of welcome.

Two excursions followed: to the Provan Chemical Works and the Dalmarnock Power Station.

The Provan Chemical Works is the largest of four units owned and operated by the City of Glasgow for the distillation of tar and ammonia, one being located at each of its gas plants. That is, the crude distillation of tar is done at the other works, whilst the refining is done at Provan. Notes on this plant and the power station will be found elsewhere.

In the evening came the banquet with President Ruttan as Toastmaster and the Lord and Lady Provost of Glasgow and about 300 persons all told. The toast were "The King", "The Queen, the Prince of Wale and members of the Royal Family," given by the chai man. A song followed by a Scotch lass who claime she was lonely, but we doubt if she is likely to suffe much from that complaint. "The Society" was give by the incoming president, Dr. E. F. Armstron F. R. S., and son of the medallist of the morning, t which the chairman replied. "The City of Glasgow was given by Sir William Pope, and it was the mo humorous after-dinner talk we have heard in a mont of Sundays, with a few extra years thrown in to boo The Lord Provost replied and Mr. Ninian McWhanne told a story in Scotch dialect which he said he woul not make "vera broad"; but for purposes of unde standing we need our Scotch dialect narrower. M E. V. Evans, the Treasurer of the Society gave toast to the Glasgow Section and Mr. J. H. Young, th chairman, responded. Professor G. G. Henderson, Hea of the Department of Chemistry at Glasgow Universit tosated the visitors, and the consulting editor of *Che and Met.* replied. Then, with "Auld Lang Syne" th meeting closed.

General Subject Usually Covered in Papers

Thursday began with moving pictures of chemic industries for some and a visit to the harbor f others. A similar informal luncheon at the Grosven followed, with Mr. J. Arthur Reavell in the Chair, a in the afternoon the chemical engineering group he a session at which the following papers were presente "Observations on the Design of Ammoniacal Liqu Stills," by Mr. P. Parrish and "Tar Distillation," Mr. W. A. Walmsley. In the evening Prof. J. Hinchley discussed the general theory of evaporati and Mr. T. H. Gray glycerine distillation. These ve interesting papers are presented in abstracted form the following pages.

The so-called chemical engineering group is an acti association within the body of the Society of Chemic Industry. At these meetings upward of two hundr were present, and the business was handled with co summate skill. They are organized to cover a gener subject, as in the present instance, evaporation a distillation. A chairman is selected who is special familiar with the matter under discussion and aft a paper has been presented he knows his audience w enough to call on the right people. They ask questio with delightful frankness and are not afraid to expre their opinions. There is hardly a dull minute at the sessions.

Technical Program

A Rapid and Accurate Method for the Calculati of Storage Tanks

By J. W. McDavid, D.Sc., F.I.C.

The volume of storage kettles are usually determin either by measuring the vessel and calculating t volume, or by filling the vessel with water and weig ing the water as it is run out of the tank. The fi method is accurate only for symmetrical tanks of co stant vertical cross section. The second method extremely cumbersome. Still another method is to a tank with water and add a weighed quantity of n soluble salts. The resulting solution is analyzed and t volume calculated in this way. This becomes ve laborious if the volume per inch is desired. Anoth

ethod has been worked out by J. M. Weir, N. Taylor d the author, which consisted of the following items own in Fig. 1. A small cylindrical vessel (*A*) 4 ches in diameter and about 2 feet 1½ inches in length open at the top and is held in a vertical position by eans of three legs (*B*), each of which carries a level- g screw (*C*). A plumb line is provided to insure at the apparatus is set vertically. Water is supplied the apparatus through the ¾-inch inlet cock *D* to nich a hose pipe can be attached. *E* is a brass over- w pipe ¾-inch in diameter while *F*, a pipe of similar ze, delivers the water to the tank to be calibrated.

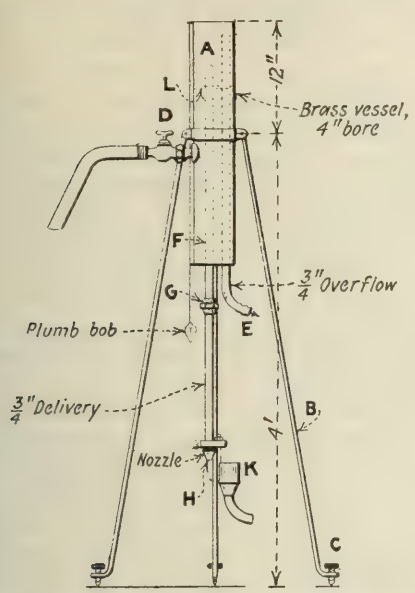


FIG. 1—APPARATUS FOR CALIBRATION OF TANKS

the first instrument this pipe was for convenience ade in two parts connected by means of a screw upling. In later instruments this coupling was nitted. The bottom of the delivery pipe is fitted th a screw thread, so as to take a nozzle *H*. Five zzles of diameter ¼-, ⅜-, ½-, ⅝-, ¾-in. respectively were ovided so that the quantity of water delivered to e tank can be varied. The funnel *K* works on a ivel so that it can be placed underneath a nozzle and divert the water from the tank which is being cal- rated. *L* is a plate perforated with holes ⅛-inch in ameter and serves the double purpose of forming a pport for the pipe *E* and *F*, at the same time reduc- g turbulence in the surface of the water. The com- ete apparatus weighs only 26 lb. and can therefore easily carried about from place to place by one rson.

Method of Using the Apparatus

The method of using the apparatus is as follows: ne instrument is set up in a vertical position over convenient inlet hose over the vessel to be calibrated. ne funnel *K* is placed under the nozzle, and sufficient ater let into the apparatus through the cock *D* until ere is a slight trickle of water escaping over the erflow pipe *E*. In the experiment carried out to libraate the apparatus the quantity of water escaping er the overflow pipe was determined and averaged to 1.5 lb. per minute. As soon as water is leaving e water pipe at the rate mentioned above, the head water in the overflow pipe has reached a constant ure. So long as a level is maintained, the quantity of water delivered through the nozzle with be constant. When this condition has been obtained the funnel *K* is drawn smartly from below the nozzle and the water is allowed to flow into the tank. At the same time a reliable stop watch is started. If it is required merely to find the total volume of tank the time taken to fill it with water is noted. But if it is required to find the volume per inch of depth, then funnel *K* is placed beneath the nozzle after a definite interval of time and the depth of water in the tank measured. By choosing suitable intervals of time, the volume per inch of depth can be calculated.

The apparatus must be calibrated with each of the five nozzles in turn by allowing the water to flow through them into a tared box on a weighing machine. The results obtained in this manner were found to agree well within any possible limit of experimental accuracy and the apparatus has been used with great success in the plant.

The General Problem of Evaporation

By Prof. J. W. Hinchley, A.R.S.M., F.I.C.

A thoughtful paper on this subject, which is divided into two main parts, first evaporation at temperatures below the boiling point and second evaporation at boiling temperatures! Most of Prof. Hinchley's work has been done on evaporation below boiling temperatures and some interesting formulas and curves are presented. This work is also of interest in studying evaporator design, inasmuch as the rate of evaporation from surfaces of various kinds plays an important part in evaporator design. Prof. Hinchley has shown that convex surfaces give a higher rate of evaporation than concave. Considerable work has also been done by Carrier in America and by Dr. Leonard Hill. The effect of velocity of gas stream is also discussed and many practical applications are pointed out as the result of this study. A discussion of vapor pressure and measurement and also of drying immediately precedes the part of the article dealing with boiling point evaporation. This discussion is very interesting and takes up the variation in the rate of heat transmission and in evaporator design. He refers to the work of Badger and others in American universities on the variations of heat-transmission from steam to boiling liquid.

Design of Ammoniacal Liquor Stills

By P. Parrish, A.I.C.

The paper does not deal with the merits or demerits of the batch-fired intermittant stills, or the distillation of ammoniacal liquors. It assumes that substantial technical reasons justify the abandonment of such plants. The present type of continuous columnar still for distillation of gas liquors can be traced to a Frenchman by the name of Savalle, who was responsible for many patents in 1875 aimed at improving the apparatus and processes for the distillation and purification and rectification of alcohol. Savalle's work was undoubtedly directed at the improvement of the Coffey still and it is interesting to note that this alcohol still was substantially taken over into the ammonia industry and used in that work. Mr. Parrish then divides the ammonia stills into three categories, distinguished by a different arrangement of the free still, the lining chamber and the fixed still. He discusses the relative advantages of these arrangements and then enters into

a detailed and very thorough discussion of the construction of stills. Finally the operating details which are necessary in continuous distillation are considered. The whole paper makes very formidable and worthwhile reading.

Tar Distillation

By W. A. Walmsley

This, as well as the last paper, originated in the Provan Chemical Works at Glasgow. Mr. Walmsley divides tar distillation into its constituent parts discussing first the variation in tar which resulted from the use of vertical retorts. The treatment of the various fractions is undertaken in detail and among other things the complete description of the Dorr continuous causticizing plant which is in use there. Some details as to the operation of continuous tar stills are given, tar being distilled over a period of 5 days, in the longer experiments. Final paragraphs deal with the benzol plants and the Kubierschky spraying.

Historical Development of the Distillation of Glycerine

By C. H. Gray

From the earliest mention of glycerine as "the sweet principle of fats", by Scheele, in 1779, through Chevreuel's classic researches about 1820, until Cap's process was introduced in 1840, very little commercial use was made of glycerine. Cap used the liquor from lime saponification of tallow in candle manufacture. After appropriate treatment, the neutralized liquor was carefully evaporated, then passed through bone charcoal, which gave a more or less pure glycerine. Later improvements by Tilghmann and Wilson made considerable difference in the process. Perhaps O'Farrell's improvement, in 1881, is of sufficient importance to mention. He used vacuum pumps for distillation, together with steam at 200 deg. C., using soap lye crude in the still. This lye was, no doubt, substantially soap crude, as we know it today, except for purity. Considerable improvement in design of apparatus was made following 1880, notable improvements by Van Ruymbeke in 1895, and by Scott. Both of them employed extremely high vacuums, as high as 28 in., and many other improvements, such as surface condensers etc.

Double and triple distillation of glycerine did not come about until recently, in order to attain high purity required by the British Pharmacopoeia. Garrigues, in 1905, and Wood, in 1907, bring the subject almost down to the most modern type of plant. Broadly speaking, we may summarize the progress made in glycerine distillation as having gone along the following lines: (1) By actual improvement in design of apparatus from an engineering standpoint. (2) Glycerine of today is practically a pure substance in so far as commercial material may be free today as distinct from earlier times. (3) Efficiency and economical use of energy are the points aimed at by our chemical engineers and designers. It is interesting to note that Lieutenant-Colonel Briggs, B.S.O., in his chapter on glycerine distillation in Young's latest volume "Distillation Principles and Processes" gives the following figures for relative coal efficiencies per ton of glycerine distilled:

Wood	13
Scott	14
Van Ruymbeke	16

As the final development in glycerine distillation, we may briefly consider the idea propounded by Société Francaise de Glycerines. This plant is so designed a to work without the use of steam. Crude glycerine a a temperature of 180 deg. C. passed in an atomize state from one vessel by means of suitable jets t another vessel. Steam coils maintain the temperatu at 180 deg. C.

We have no practical details at this time, but it evident that the idea is very unique, although at time there are some obvious troubles involved. For instanc choking of jets, removal of solids, residues etc.

Dr. Ellwood Hendrick's Address in Reply to the Toast "The Visitors"

My Lord Provost, my Lady Provost, Mr. Presiden Professor Henderson, Ladies and Gentlemen:

From across the great waters I bring you greeting and the assurance of all good will and fraternity. I sha ask you to take this statement for granted and th message as delivered, because in addition to the felic tations of ceremony and the messages from our hearts bring also a problem and seek its solution.

In what follows I shall speak only of conditions i the United States. Whether these obtain in similar c in less measure here or elsewhere in British possession you will know far better than I. The problem has t do with the great gulf that lies between the professio of chemistry and its business. As corporations gro in magnitude, this gulf threatens to become even wide and since Mr. Young touched upon the subject yesterda I venture the belief that you are not total strangers to i

We study long and ardently to attain proficiency i the science and its practice. On the other hand, n study, no proficiency, no competency, and sometime not even character, is demanded of him who woul engage in the business of chemistry. So long as he ca offer or borrow money he is welcome. This is becaus the need of chemical development is so urgent for th welfare of every industrial nation that we do not dar place hindrances in the way of it. The situation pr vides, however, that the business end rules the profe sional end. Business directs the profession in its ow field and the profession must obey. This is not tru of all chemical enterprises by any means but it occu so frequently that ignorance of the science control rules, or directs chemical practice, that I venture th general statement that in the United States the weal ness of chemical industry is not in the works, or equipment, or in labor, or in engineering skill, or the chemists themselves, but that it rests in the boar of directors of chemical establishments.

Corporations have an unfortunate habit of what w call window-dressing, in which men who have achiev success in any walk of life are supposed to assure also in chemical industry, so that a successful bank stockbroker, lumber merchant, mine owner and wh not are invited to join the board in the belief that t public will follow the mistaken idea that astuteness w conquer in spite of ignorance.

In no other great profession than ours does this sit ation exist. Imagine, if you will, a sick man sendi for a physician and on his arrival demanding that punch a time clock, coming and going, be paid acco ing to the time spent in making his diagnosis, and th he devise treatment according to the patient's wh and desire. Or of a client insisting that his counsel at law shall construe the law according to his wish a not as it is found.

The control of chemistry by business has reached uch a pass that I have known a speculator in the ndustry to destroy the entire research organization of great establishment engaged in the most difficult and nvolved scientific processes and to consult an excava- on engineer for enlightenment as to how the works nould be operated.

The future of the industrial nations rests with their hemists. According as they are more or less men f wisdom and understanding, and above all things nen of character, industry will flourish or fade away. Ve cannot ask for all of these standards from the nan who represents the investment of capital alone.

Now the last thing we want to do is to restrict the ights of property, or to destroy initiative. But chemi- al industry is a professional institution and it cannot ourish if it is ignorantly directed. Chemical vision nd understanding are required of it if it is to prosper. nd the looting of corporations by cutting off necessary xpenditures for research and technological develop- nent to use such funds for dividends, or to make a rave showing for the market manipulation of shares, is so heinous an offence against the general welfare that no self-respecting chemist should countenance it or endure participation in it.

Before anyone is admitted to the practice of medicine it is required of him that he take a solemn oath to devote himself to human welfare. A solemn oath of allegiance to the principles of right is required of everyone who would practice at law. At present chemists pass examinations—and look for a job. This does not meet with the great obligations of our profession. So, as a possible means to secure a better status for the profession of chemistry in its own affairs, I venture to suggest that an Oath of Science be drawn and administered to everyone who would engage in chemical practice. He should bind himself on honor to seek diligently the truth by the right co-ordination of all facts which alone leads to it, to abstain from all knavery under any and all conditions, and to address himself to the welfare of humanity, striving throughout his days to seek the light of greater understanding and to bring about a larger, a better, and more abundant life for all mankind.

Calcium Arsenate Manufacture

By Howard W. Ambruster

THE suddenly developed and more or less acute shortage of calcium arsenate available for the battle vith the boll weevil in the South has intensified the nterest in this product.

The market record of this insecticide has been so rratic in the past that despite all indications months go, of an increasingly heavy infestation and conse- uent demand, the manufacturers refused to accumulate ny stocks in anticipation of the season's requirements nd waited until there was an actual movement by sale r contract of the several thousand tons carried over rom 1920 and 1921.

The bulk of these stocks had the status of a distressed nerchandise and were sold in the early months of this eason at a price considerably under the actual cost of roduction during the high level of the inflation period. 'his assisted in completely demoralizing the market as ar as current production was concerned and it was ot until the last few weeks that it was generally real- zed that all old stock would be absorbed and still permit ctive demand for any additional tonnage the existing lants could turn out during the balance of the season.

Indications are now that dusting for boll weevil con- rol will continue well into September, thus compelling he manufacturers to operate their plants to full apacity during the hottest months of the year.

The Same Old Story in Insecticides

It is the old story in the insecticide industry—a feast r a famine year after year; high surplus stocks to arry over and liquidate on a declining arsenic market; r a sales department weeping and gnashing its teeth t the necessity of declining a flood of last moment rders at high prices, an account of earlier commitments t selling prices that preclude any profit.

As an insecticide, however, calcium arsenate is in a ass by itself as it promises a real tonnage development nd as the natural consequence of this season's dramatic imax, plans for additional plant facilities are now nder consideration among all existing manufacturers and many localities in the South are discussing ways and means of building calcium arsenate factories and taking care of their local requirements for next season.

Consideration of additional plant facilities must be based generally on the usual chemical process of utilizing commercial byproduct white arsenic oxidized with nitric acid and combined with lime. The possible production of calcium arsenate direct from an arsenical ore must be considered as having a bearing on the subject but in view of the recent excitement in the South due to the short supply this season, the future development of this new chemical process will hardly prevent others from increasing old plants and building new ones in anticipation of next season's demand for calcium.

The Executive's Dilemma

For the manufacturer who has been in the insecticide business and has any perspective on its many problems, the picture at this time presents many of the aspects of a seven-ring circus. He does not dare concentrate his gaze on only one part of the performance and his vision is confused as he tries to take it all in at once. He knows that it is a slippery hill, but he is bound to try and climb it. For the newcomer in the field the problem may appear much simpler and the hill not slippery at all. All that seems necessary is to raise a little capital, build a plant, buy some lime and arsenic, and when next season's bugs appear there will be a new local hero. But the problem is not so elementary as all that by any means.

There is no question, however, that there is room for a considerable increase in the production of this material and that unlike most of the orchard and truck sprays, calcium arsenate is coming into its own as a tonnage proposition. The existing plants where it is now made, or can be made, have nearly all developed from small units for the production of miscellaneous arsenical and other spray materials such as paris green, london purple, lead arsenate, bordeaux mixtures, etc.

Early Calcium Arsenate Plants

Calcium arsenate was first made in comparatively recent years, along with other similar products as the insecticite manufacturers decided to add it to their line

and few radical changes were introduced from earlier equipment or methods for arsenical compounds. The first of the arsenical sprays to be made on any basis of quantity in this country—paris green—was originally included with the pigment colors and small earthenware units for the oxidation of white arsenic to make the necessary arsenic acid, were added later for the production of lead arsenate.

Recent Developments

In the last few years, two important and somewhat radical improvements have been developed in insecticide manufacture, one in the acid production and the other in reducing the wet batch of lead or carcium arsenate to a commercial dry powder.

The majority of the arsenic acid plants as stated above were of earthenware construction, comparatively small pots in which the commercial white arsenic is oxidized with nitric acid and a part of the nitric fumes recovered in an earthenware tower or series of towers, to be utilized again with subsequent batches of arsenic.

A great deal of hand labor is required for the operation of these plants. The arsenic must be fed by hand in small quantities; such stirring as the batch gets is by hand and the sludge or residue removed by hand after the finished acid is syphoned out of the pot or generator. The breakage item is a heavy one and adds materially to the cost of the acid. The quality of the white arsenic always varies somewhat and thus affects the recovery of the nitric acid by inducing an erratic and explosive reaction which is accentuated by the irregular hand feeding. This results in sudden bursts of gas which the suction from the recovery towers cannot handle.

High Silica Iron Aids Arsenic Acid Process

Preceding and during the war period, the use of high silica iron for large nitrating kettles was developed and large units of this material were adapted for arsenic acid manufacture. This has made it possible to produce the material in very much large batches and to introduce mechanical feeding of the arsenic itself, mechanical stirring of the batch and dropping the finished acid with the sludge or residue from the bottom of the kettle to a shallow tank where the sludge is settled out and the acid pumped to storage or insecticide units. The economy of both labor and nitric recovery are considerable and the production of a nitric-free arsenic acid which can be safely shipped in steel tank cars was first made commercially feasible by this method.

Another radical departure which is applied to advantage in large arsenic acid units is the substitution of the acidproof brick masonry nitric acid recovery tower for the round terra cotta-tile tower construction. The brick tower is hardly to be considered for a small unit but for anything over the production of a few tons of arsenic acid per day, its advantages of stability and efficiency must be given consideration.

In the production of the insecticides themselves, the usual process necessitates the large tubs with mechanical stirring apparatus in which the finished product is combined in a very dilute suspension. The size and material of the tubs and the methods of handling the various raw materials may vary somewhat but the essential features must remain the same.

The New Drum Drier

Beyond these mixing or striking tubs, however, the other definite step forward has been taken in the substitution of a specially designed atmospheric drum drie for the filter presses and hot stoves, oven or tunne driers of the old fashioned pigment plants. We mus go back here to the brick ovens filled with steam pipe of the European color plants and their successors, th modern hot air tray driers in which the filter press cak is baked until the last drop of moisture in the cente of the cake is evaporated. For many products thes modern driers scientifically designed and properly oper ated are still the most efficient units available. Bu for products like lead and calcium arsenate which ar beginning to be handled on a tonnage basis the labo saving affected by means of the atmospheric drum drie is a very large item in proportion to the total labo cost of the material.

Economy of Drum Drier

Instead of pumping the batch first to a filter pres and then handling the cake on trays first in and the out of the drier, the liquor is simply pumped to th drum drier, where it is picked up from a trough o the surfaces of the hot cylinder and the water i evaporated by the time it reaches the scraping knif on the lower downward turn of the drum. The produc comes off in a fine flake which requires very littl grinding as compared with filter press cake dried in tray drier and a power saving also results at the grind ing mill. The question will naturally be raised as t the amount of steam required for the drum drier t evaporate the entire moisture content of the batch whereas in the older method a definite percentage o the water is removed at the filter press. Experienc with the arsenates has demonstrate, however, that th greater efficiency of the effective heat units as applie to a thin film of liquor on the drum rather than as hot blast forced through and around a filter press cak results in no greater coal and steam consumption fo an equal amount of dry production, and in some in stances an actual coal saving is found.

Importance of Improved Methods

The writer was fortunately in a position to observ these various methods of arsenic acid and insecticid production in the same plant, having supervised th actual construction and operation of both the older an the newer types of units and the comparative result were so conclusive that the advantages set forth abov must be accepted as demonstrated facts. The qualit of both the arsenic acid and the finished insecticid was improved, if anything and the material and labo saving constituted a tremendous item in proportion total cost. Chemical manufacturers are frequently loat to throw out existing units before the scrap hea claims them but the controversy regarding these in provements in the production of arsenicals bids fair be settled in the immediate future with the enlarg ment of existing plants and the construction of ne ones for the struggle against the future progeny the 1922 boll weevil. There can be a variable co factor of several cents a pound on a half-pound packa of orchard- or garden-spray and the salesmanship good will of the manufacturer will get or hold the cu tomer. But boll weevil marches in the millions modern warfare and from the chemical manufacture standpoint, this pest must be fought on a carload ba where a difference of a few dollars a ton will deci each producers' part in the contest.

The Technology of the Carbon-Electrode Industry—II
Raw Materials for Electrode Manufacture

The Physical and Chemical Properties of the Carbonaceous Substances and Binding Materials Are Reviewed From the Standpoint of Electrode Requirements—Petroleum Coke and Pitch Are the Principal Raw Materials for the Carbon Industry*

By Charles L. Mantell
Division of Industrial Chemical Engineering, Pratt Institute, Brooklyn

As a carbon electrode consists almost entirely of elemental carbon, it naturally follows that the best starting point for its manufacture would be a material which contained the largest possible amount of carbon. A raw material would be desired which consisted almost entirely of carbon. This condition is satisfied by those bodies which are known under the general name of carbonaceous substances and, as a matter of fact, practically all carbonaceous matters are, or have been, used in the manufacture of electrodes.

Electrode Requirements

Before attempting a detailed description of the various raw materials, it may be well at this point to devote brief attention to the characteristics and desired qualities of the finished electrodes in order that the raw-materials requirements may be better understood.

In general commercial electrodes consist of elemental carbon, contaminated with more or less ash depending upon the raw material used in making the electrode. The ash is composed of the oxides of silicon, iron, aluminum, calcium and in some cases of copper. The resistivity—i.e., specific electrical resistance—expressed in ohms per inch cube, varies with the ash content; the higher the ash percentage the greater the resistivity, other factors remaining unchanged.

Electrodes for electrothermic work usually have high resistivity. They serve as refractory conductors of the electric current and do not enter into the reactions taking place in the electric furnace or other apparatus in which they are used. The manufacture of calcium carbide is an example of an electrothermic requirement. In this case the raw materials are coke and burnt lime. These are cheap and impure, for the coke contains a large amount of ash. It does no harm, therefore, to use an electrode high in ash in the furnace, for the additional amount resulting from the consumption of the electrode would probably be decomposed by the heat of the furnace itself. Electric steel or electric-furnace alloys are other examples. In these, contamination from the electrode would be drained out of the furnace with the slag or dross and would not get into the product. In most cases of the electrothermic use of carbons, the impurities of the electrode either do not get into the product of the furnace, or if they do, make no appreciable difference in the product. Thus a satisfactory electrode for electrothermic purposes may be high in ash, since its resistivity is either unimportant or else can be sacrificed if, by so doing, a cheaper electrode may be employed.

In electrolytic work, however, the purity and resistivity of the carbons are important considerations. Smaller currents are used at much lower voltages, so that high resistivity means a greater power loss than in electrothermic work. Furthermore, the material of the electrode may enter into the reaction and its impurities be imparted to the product of the electrolysis. An example is the reduction of alumina to aluminum. In this case the impurities of the electrode, if present in too great amounts, cause serious contamination of the aluminum metal. Silicon and iron are particularly undesirable. It is desired that carbons for electrolytic use have a low resistivity and be as free as possible from contamination.

Classification of Raw Materials

Raw materials for carbon-electrode manufacture may be divided into three classes according to the part they play in the process: (1) "Body" materials, which are the carbonaceous matters making up the bulk of the finished electrode. (2) Binders, which serve to hold together the finely ground particles of the body materials, and (3) other miscellaneous substances entering into the manufacturing process.

TABLE I—A COMPARISON OF CARBONACEOUS SUBSTANCES USED AS BODY MATERIALS IN ELECTRODE MANUFACTURE

Material	Moisture, Per Cent	Volatile Matter, Per Cent	Fixed Carbon, Per Cent	Ash, Per Cent	Specific Gravity
Coal:					
Anthracite	2.4–14.0	1.5– 8.5	65.0–85.0	6.0–18.0	1.5
Bituminous	1.8–19.0	6.0–40.0	49.0–79.0	2.8–19.0	1.36
Coke:					
Beehive	0.5– 1.5	0.3– 3.0	80.0–95.0	4.0–21.0	1.9
Byproduct	0.7– 3.0	0.6– 3.3	79.0–92.0	7.0–16.0	1.7
Petroleum coke	0.4– 2.0	4.0–18.0	82.0–97.0	0.5– 2.0	1.8
Retort and gas carbon	0.5– 2.0	4.0–13.0	88.0–97.0	3.0–10.0	...
Graphite, natural	0.5– 2.0	1.0– 7.3	78.0–92.0	7.5–19.7	2.0– 2.5
Pitch coke	0.5– 1.5	4.0–12.0	85.0–97.0	0.3– 2.0	1.6– 1.8
Wood charcoal	1.0–10.0	1.0–10.0	84.0–97.0	1.0– 4.0	...
Lampblack	0.6– 3.0	3.0– 7.0	90.0–96.0	0.6–10.0	...
Butts, amorphous, from electrothermic work	0.2– 2.0	0.0– 0.2	85.0–94.0	6.0–14.0	1.9– 2.2

The composition of the various body materials which are, or have been, used in the production of carbon electrodes is shown in Table I.

The Body Materials

Anthracite and Bituminous Coal

Anthracite coal contains a large amount of fixed carbon as compared with its content of volatile matter. The ash is incombustible mineral matter, consisting mostly of clay, silt or sand, more or less intimately mixed in the body of the coal. Anthracite is used largely for electric-furnace electrodes where purity and low resistivity are not desired. In fact, very little else

*Part I of this series, which reviewed the history of the industry, appeared in *Chem. & Met. Eng.*, vol. 27, No. 3, July 19, 1922.

other than anthracite coal is used in making the large-sized molded electrodes for electric furnaces.

Jean Escard[12] gives the following data in regard to European practice in the purification of anthracite for use in making electrodes for the reduction of aluminum. "Anthracite in general contains more than 2 per cent of ash, of which at least 0.35 per cent is silica. This latter figure is inadmissibly high for the production of aluminum, but when purified such anthracite shows the following ash figure before and after treatment (anthracite is first degassed in one of the standard illuminating gas ovens, the gas being burned under the grate):

Constituents of Ash	Scotch Anthracite — Previous to Treatment, Per Cent	Scotch Anthracite — After Treatment, Per Cent	Welsh Anthracite — Previous to Treatment, Per Cent	Welsh Anthracite — After Treatment, Per Cent
SiO_2	5.00	0.84	0.78	0.20
Iron oxides	1.06	0.25	0.32	0.12
Al_2O_3	2.02	0.25	0.43	0.12
CaO and MgO	1.16	0.20	0.53	0.13
Total	9.24	1.30	2.06	0.57

The chemical treatment referred to by Escard consists of digesting the ground anthracite in a hot concentrated NaOH solution, and following this with a washing with a more dilute solution.

In the United States a much purer raw material can be obtained at a lower price than the cost of the purified anthracite would be, so that this method of purification is not used. In this country petroleum coke is the chief raw material for graphite electrodes which are made by graphitizing in the electric furnace.

Bituminous coal is high in volatile matter, containing a much smaller amount of fixed carbon in proportion to the volatile matter than the anthracite. It also runs high in ash. Since large losses are sustained in driving off the volatile matter in calcination and since the gases generated cannot usually be profitably disposed of by an electrode plant, bituminous coal is seldom used as a raw material. It has the further disadvantage of having a lower specific gravity than anthracite. Some of the first electrodes made for metallurgical work were prepared from a mixture of bituminous and anthracite coal, but the practice has since been abandoned.

Coke prepared from bituminous coal is high in ash content, high in fixed carbon and low in moisture and volatile matter. It is used in Europe for electrodes for electrosmelting, but to a much less extent in the United States. Coke is not employed in making electrolytic carbons.

Petroleum Coke

Petroleum coke, the residue in the distillation of petroleum oil by the intermittent process, is the most important material for electrode making. It is a hard and brittle substance, of shiny, oily appearance, is very high in fixed carbon and low in ash. It is one of the purest forms of carbon available in large quantities. Its ash is probably due to the small amount of fine sand carried along mechanically or in suspension by the crude oil. The coke represents approximately 1 per cent of the original oil and from 8 to 9 per cent of the weight of the final residual tars after all of the other fractions have been distilled.

Sulphur is one of the undesirable constituents of petroleum coke, and is greater in coke from Mexican crude oils than from those obtained from other fields.

[12] *General Electric Review*, Schenectady, N. Y., November-December, 1918.

Not many years ago petroleum coke was merely a byproduct—if not a waste—in the oil industry, and was disposed of by burning it under the stills. In recent years, however, the market price has nearly trebled, and today the petroleum refinery regards it as a valuable commercial material. The quantity of petroleum coke being produced is growing smaller, however, because many oil distillers are changing over from intermittent to continuous or vacuum methods whereby no coke is produced. This change is already causing electrode manufacturers to search the field for new sources for their raw material supplies.

The percentage of volatile matter in petroleum coke depends upon the temperatures reached in distillation. Present practice is to run the stills to as high a temperature as possible without actually damaging the bottoms of the stills. Pyrometric control methods are not used nor is any attempt made to control the percentage of volatile matter in the coke produced.

After the run is finished, the still is allowed to cool for 4 to 6 hours. Workmen then enter through the manhole, their hands, head and feet wrapped in wet cloths, break off the coke with heavy iron bars from the sides and bottom of the still box, and unload it. Because of the excessive heat, the men can remain inside the still for only a short while. The coke is cooled by drenching with a stream of water.

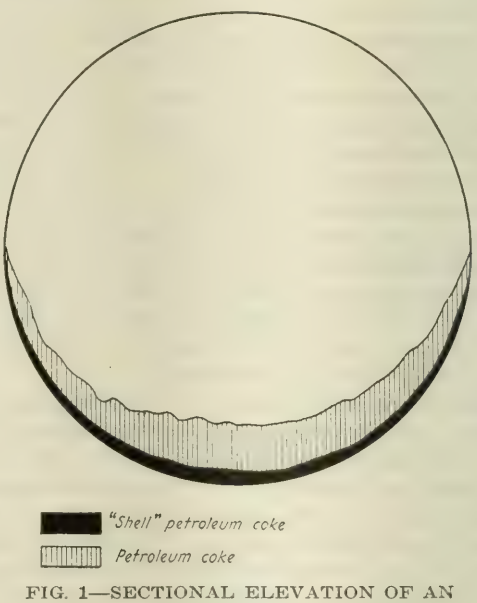

FIG. 1—SECTIONAL ELEVATION OF AN INTERMITTENT-TYPE OIL STILL, SHOWING COKE FORMATION

Petroleum coke is received at the electrode plant in pieces varying in size from as small as 3 in. in diameter to chunks three or four times as large as a man's head. The coke consists of two portions, the main or upper part and beneath it a layer of denser material, called "shell," varying from eggshell thickness in some pieces to 2 to 3 in. This shell is the coke that was in contact with the sides and bottom of the still (see Fig. 1). It is higher in ash and soluble salt than is the coke of the upper portion, probably because the mineral matter of the oil gradually sank to the bottom of the still as the distillation proceeded and the shell, being the first coke made, formed around the mineral matter. Being nearer the source of heat and the bottom of the still, the shell was heated to a higher temperature and lost more of its volatile matter than did the upper portion.

Shell petroleum coke usually contains from 1 to 3 per nt of soluble salts, mostly sodium chloride. When ke containing shell is calcined in silica brick-lined torts, the salts are volatilized and attack the brick-ork by forming low-fusing sodium silicates. In order save the retorts and lengthen their life, the shell is ipped off and separated from the main portion of the ke, to be calcined in special calciners by itself. The l distillers formerly prepared coke in this manner, but recent years have refused to ship anything but chipped coke, as the cost and trouble of chipping was t justified by the price they received for the mate-al.

A short time ago a manufacturer of carbon brushes as in the market for 25 to 30 tons of petroleum coke, d on attempting to obtain this amount from the oil stillers learned that they had none for sale. Their tput in its entirety had been contracted for a year in vance by electrode makers. The contracts of one of e largest electrode plants called for the delivery of proximately 50,000 tons of petroleum coke during the ar. This amount is the result of the distillation of 000,000 tons, or 31,250,000 bbl. of crude oil.

Petroleum coke is used more than any other material making the purest electrolytic carbons. These elec-odes are low in ash and low in resistivity. For the wer grades, where exceptional purity is unnecessary, troleum coke is mixed with anthracite. This enables e manufacturer to turn out a cheaper electrode but of rer composition than if he had used anthracite alone.

Retort and Gas Carbon

Retort carbon, or "glance" coal, is a very dense form carbon, produced by the deposition of carbon in the per part of the retorts in the manufacture of coal s. It exhibits the luster of a metal, is sonorous when ruck and is a good conductor. Ordinarily it is rich in ica, the result of adhering fragments of brickwork d refractory pastes from the retorts. The amount of tort carbon on the market, however, is very small. ree years ago a canvass of several hundred gas-nufacturing plants in the East was made to deter-ne the amount of this material available. Quantities nging from 1 to 25 tons per year were offered—this ing the entire production of the individual gas works at prices from $20 to $30 per ton. For most of the s makers, the price received for the material would t have paid them for their trouble in accumulating from the periodical cleaning of the retorts. The price ked was considerably higher than the market price petroleum coke, a much purer substance.

Because of the difficulty of obtaining large quantities well as its high price, retort carbon is seldom used making electrodes. It finds its greatest use in the nufacture of carbon brushes, where its hardness and e sharp edges of its particles are employed to give a ting grain to the texture of the brush.

Other Body Materials

Graphite. Graphite, of the natural variety, is not ployed in the United States for the manufacture of ctrodes, first, because of its high price ($120 to $180 r ton) and, second, because the artificial product, de directly by graphitizing electrodes in electric fur-ces, as a result of its superior qualities, is given pref-nce in practice.

Pitch Coke. Pitch coke has much the same qualities petroleum coke. It is produced as a result of the destructive distillation of pitch, which comes mostly from coal tar. It is low in ash and high in fixed carbon. At the present time it is not being produced in large quantities. Its production, however, is gradually increasing with the demand. In every place in which petroleum coke is now used it can be replaced by pitch coke. As the supply of petroleum coke grows less, due to the changed methods of oil distillation, its place will probably be filled by pitch coke. What is needed is the production of a pitch coke with a volatile matter so low (0.5 per cent) that it needs no calcination to prepare it for use in electrode making. This has been done, but not as yet on a commercial scale.

Wood Charcoal and Lampblack. These substances were used by some of the earlier investigators. They are low in ash and high in fixed carbon. Their high price, however, and the fact that they are produced in relatively small quantities prevent their utilization in electrode making.

Butts. Butts are the unconsumed or waste portions of finished electrodes. They are usually high in ash. They are used in making electrothermic carbons, and are mixed in low percentages with petroleum coke for electrolytic electrodes. Usually, however, they are given a preliminary purification. As they are portions of electrodes previously baked, they need no calcining operation to prepare them for use.

TABLE II—COMPARISON OF APPROXIMATE PRICES OF CARBONACEOUS MATERIALS, f.o.b. NEW YORK (1922)

Materials	Dollars Per Ton
Coal:	
Anthracite	8.00@ 9.00
Bituminous	3.50@ 4.00
Coke:	
Beehive	5.50@ 6.00
Byproduct	4.50@ 5.50
Petroleum coke	12.00@ 15.00
Retort carbon	25.00@ 30.00
Graphite	120.00@180.00
Pitch coke	Not on open market
Butts	20.00@ 40.00

A rough comparison of prices for the most important carbonaceous materials which are or may be used in electrode manufacture is afforded by Table II.

Binding Materials

Binders for electrode making are divided into three classes; those which at ordinary temperatures are either (1) liquid, (2) semi-solid and (3) solid. The principal binding materials which have been used in the manufacture of carbon electrodes are:

(1) Liquid:
  (*a*) Tars.
    (1) Retort-gas tar.
    (2) Oven-gas tar.
    (3) Water-gas tar.
(2) Semi-solid:
  (*a*) Electrolytic pitch.
(3) Solid:
  (*a*) Coal-tar pitch.

Chemical analyses of these substances are given in Table III.

The binders used are, in general, products of the distillation of coal. They are composed of elemental carbon and hydrocarbons in varying proportions. Their function is to hold together the finely ground particles of the body materials. Since the volatile matter of a binder is driven off in baking, the best binder, from the standpoint of the finished electrode, would be the one

TABLE III—CHEMICAL ANALYSES OF BINDERS USED IN ELECTRODE MANUFACTURE

Material	Melting Point, Deg. C.	Viscosity (MacMichael) (Seconds Per 100 Revolutions)	Free Carbon, Per Cent	Coking Value, Per Cent	Softening Point, Deg. C.
Coal tar	Liquid	3–15	7–25	10–30	.....
Retort gas tar	Liquid	5–30	20–40	40–65	.....
Oven gas tar	Liquid	3–15	12–20	15–30	.....
Water-gas tar	Liquid	3– 8	2– 5	10–20	.....
Pintsch or oil-gas tar	Liquid	....	25–30	25–35	.....
Electrolytic pitch	Semi-solid	3–25	15–25	20–35	20
Pitch:					
Soft	50–70	3–35	15–25	20–35	35–60
Medium	70–90	15–40	25–35	30–40	50–80
Hard	90–140	20–250	30–50	35–55	80–115

that had the highest coking value; or, in other words, loses as little as possible during calcining.

The earlier investigators used many different viscous matters to hold together their carbonaceous materials. These included caramelized sugar, sirups, molasses, resins, turpentine and various products from the distillation of organic substances.

Viscosity is more or less a measure of the binding power of a material. Viscosities are not absolute figures (unless absolute viscosities are used, reported in dynes per centimeter) and serve only as comparisons, one to the other. A binder with a high viscosity will tend to have a greater cohering power than one with a low viscosity. In measuring viscosity, either the Sturner, also known as the MacMichael, or the Engler types of instrument are most commonly used.

Tars

Coal Tar. This material is too well known to require any extensive description of its properties. It is a black, viscous liquid, composed largely of hydrocarbons, with a low percentage of "free" or elemental carbon. It varies greatly in composition, and may better be classified according to its method of production into retort-gas tar and oven-gas tar. Coal tar used in making electrodes is usually a mixture of tars from different sources. Its viscosity is low; in the case of some thin tars, it can be measured only with difficulty in the MacMichael instrument.

Retort-Gas Tar. This tar is obtained as a condensation product in the hydraulic mains, scrubbers or condensers in the manufacture of coal gas for illuminating purposes. It is less fluid and contains less of the lighter hydrocarbons, more naphthalene, anthracene and their accompanying oils and more free carbon than tars from other sources. The composition varies with the heats and coals employed. In general, the lower the carbonization temperature of any coal the more fluid the tar and the lower its carbon content.

Retort-gas tar contains 20 to 40 per cent of free carbon and yields on distillation from 50 to 75 per cent of pitch, or if the distillation is carried all the way, 45 to 65 per cent of coke.

Oven-Gas Tar. This material is obtained in the distillation of coal in byproduct coke ovens. It is similar to retort-gas tar, except it is more fluid. It contains more of the hydrocarbons and considerably less free carbon, which latter usually runs from 12 to 20 per cent. The composition changes, of course, with the coal, type of oven and the coking temperature.

Water-Gas Tar. The tar obtained from the manufacture of carburetted water gas for illuminating purposes differs mainly from coal tar in the entire absence of tar acids and ammoniacal liquor, and in the small amount of free carbon present, which is usually less than 2 per cent.

Water-gas tar on distillation yields from 35 to 60 per cent of pitch, or, if carried further, 20 to 40 per cent of coke of the weight of the dry tar.

Pintsch or Oil-Gas Tar. This material comes from the manufacture of oil gas used for railway lighting. It is similar to water-gas tar, but contains much larger amounts of free carbon, frequently 25 to 30 per cent or even more.

Coal tar, being usually a mixture of some or all of the above tars in varying proportions, is largely used in the manufacture of molded electrodes where great pressures are required, sometimes running as high as 25,000 lb. to the square inch. Tar is never used alone as a binding material in making extruded carbons, since tar binder mixtures are practically unextrudable. Dehydrated tars, containing less than 0.5 per cent of moisture, are mixed with pitch. Tar is often employed to lower the melting points of pitches, and in small percentages, to give a more plastic mix for extruded electrodes. Where high-density carbons are desired, its low coking value is a disadvantage. Its use produces an electrode high in porosity, since a large proportion of it is volatilized during the baking process.

Pitches

Electrolytic Pitch. This material is the result of the partial distillation of tar, in which only the lighter fractions are driven off. It is semi-fluid at ordinary temperatures and its properties are intermediate between those of tar and pitch. It is higher in free carbon and has a higher viscosity than tar. For a number of years it was used in some localities for making molded carbons but is no longer produced in large quantities.

Pitch. Pitch is the residue obtained in the distillation of coal tar after all the light oils, intermediate fractions and heavy oils (creosotes, anthracene, etc.) have been distilled.

Pitches may be classified, according to their melting points, into (1) those which at ordinary temperatures are soft and easily melted, (2) those which are midway between soft and hard and (3) those which are hard and require a much greater amount of heat to convert them to a liquid condition. This division is purely arbitrary. Soft pitches run from melting points of 50 to 70 deg. C.; medium from 70 to 90 deg. and hard pitches from this point to 140 deg. or higher. Over a wide range of melting points, the free carbon content and the coking value will increase with the melting point of the pitch. The same holds true for viscosity. Neither of these generalizations applies, however, over small ranges of melting points.

In making extruded electrodes pitches are used as binders, to the exclusion of practically all other substances. They are often employed, in small proportions, to stiffen the mix, especially in making molded carbons with a tar binder.

Selection of Pitch for Electrode Manufacture

Pitches are made by three methods of distillation.

(1) Tar is distilled to a hard, "core" pitch of high carbon content and with high melting point (150 deg. C. or higher) and then "cut back" with tar distillate to give a pitch with the required melting point.

(2) Tar is distilled to the required melting point under vacuum by the use of steam in the still. The steam assists in removing the high-boiling oils and helps to prevent the deposition of coke on the sides of the still.

(3) Tar is distilled in direct-fired horizontal stills rrying on the process without steam or vacuum and cting the products of distillation pass off under the essure at which they were generated.

For extruded electrodes, large-scale experiments have own that pitches made by the second and third ethods are superior to those made by the first. The lection of tar distillates to be used in thinning down tches, carried to the full limit of distillation (method is especially important, since it has been found that nen creosote or naphthalene are employed for this rpose the resulting pitch is lacking in binding power. nis defect is obviated only by the use of heavier dis-lates, such as "green" oils of a more viscous char-ter.

Pitch is normally about two-thirds of the weight of e tar from which it was distilled. Its physical char-ter is mainly dependent upon the temperature em-oyed in distillation, but its ultimate chemical analysis governed by the tars used in its manufacture and the ality and composition of the coal from which the rs were produced.

About the only other material entering into carbon aking is so-called "summer" oil. This is a crude troleum oil from which the lighter fractions have en distilled. Since it produces a more plastic mix it often used as constituent of the mix for extruded rbons in order to cut down the pressure necessary r extrusion. It has no binding properties. When it used it cuts back the pitch and lessens its binding wer.

Handling and Storage of Materials

The carbonaceous materials are received at the plant gondolas and are usually unloaded into track hoppers, hich in turn are emptied by pan conveyors. Coal is rchased in run-of-mine size, petroleum coke just as it as broken out of the still, and butts as they were pro-uced in the electrode-consuming processes. The mate-als are given a preliminary crushing in jaw or roll ushers to a 3-in. size and either carried direct to the lcining operations or are placed in storage.

Tars are usually stored in underground tanks, to hich they can be unloaded from tank cars. The same olds true for summer oil. Pitch is commonly shipped box cars. It is in the sizes in which it was removed om the stills and must be given a preliminary crush-g in a roll or gyratory crusher.

Materials as received are sampled for chemical alysis and these are prepared for the laboratory by ie methods of the Bureau of Mines.[13] The carbo-aceous substances are analyzed for moisture, volatile atter and ash, if they are to be used for electrothermic rbons; and in addition, for iron and silicon if em-oyed for electrolytic electrodes. Binding materials e tested for melting, and softening points if they are lid; viscosity, free carbon, and coking value. The alytical procedures in the case of the tars may be und in any standard handbook on this subject.[14]

The third article of this series will appear in a sub-quent issue and will discuss the calcining operations r electric- and gas-fired calciners with special reference their use in American practice.

[13] G. S. Pope, "Methods of Sampling Delivered Coal," Bulletin 6, U. S. Bureau of Mines.

[14] Such, for example, as that of J. M. Weiss, "Examination of rs and Tar Products," published by The Barrett Co., New rk City.

How the Cement Industry Educates Public on Uses of Its Product

By Thomas J. Harris

THE Portland Cement Association, with its staff of 300 men, most of whom are engineers, is, I believe, the largest association of its kind. Briefly stated, the work of the association is to improve and extend the uses of concrete, which implies educational, promotion and research work. Obviously so small a staff could not make personal visits to more than a very small percentage of concrete users, so the Association has become a somewhat prolific publisher on the subject of "How, Where and Why to Use Concrete." More than 100 treatises or booklets are kept constantly revised for those who are in need of information and, as in all other activities of this organization, no charge or fee is made.

Technical men will readily understand the need for such work as the association does; the user of cement must manufacture his house or well-curb or road right on the ground. It is a chemical and also an engineering process, and though simple, needs close attention and supervision.

The Association is a purely voluntary organization. Any cement manufacturer may belong to it; none need belong. At present eighty-five independent companies are members. Practically all of the cement manufacturers in the United States and Canada do belong and there are foreign members in Cuba, Mexico and South America. These foreign firms become members because of the far-reaching effect of the educational work and the value which cement manufacturers placed upon it as an aid to stabilizing and expanding the market for their product.

The Birth of a Cement Association and Its Raison d'Etre

The inception of the Association is interesting. In 1902 several portland cement manufacturers met at a dinner in New York to discuss a common problem—empty sacks. With the change of the shipping container from the wooden barrel to the returnable cloth sack came the difficulty of getting the sacks back to the mill whose brand they bore. Out on the job, two or more brands of cement might be in use, and the builder seldom took the trouble to bundle separately the empty sacks of different brands. From serving as a clearing house for empty sacks, the meeting grew into a forum for the discussion of other common problems in cement manufacture.

The greatest problem was that of getting the public to use more cement. More mills were being built and operated than could find a market for all of their capacity. Several small associations of cement manufacturers in various parts of the country had been organized, and in 1904 these united to form the Association of American Portland Cement Manufacturers—the first really national organization. One of the great problems of that time was to make the product conform to the many different specifications under which cement was made. Almost every construction engineer prepared his own specifications and the provisions which had to be met were as many and as varied as the names of the engineers. The association appointed a committee on specifications to co-operate with the

American Society for Testing Materials, the American Society of Civil Engineers and the United States Government toward much needed standardization of specifications.

The difficulties about conflicting specifications for portland cement have now been cleared up through this liaison. Standard specifications are agreed upon which are now recognized throughout the United States. By a subsequent amendment to its bylaws, membership in the Portland Cement Association cannot be retained unless the product of the mill conforms fully to the specifications for portland cement as adopted. Thus membership in the Association has become a badge of quality.

Growth and Enlargement of Scope

In 1905 an office with a permanent secretary was opened in Philadelphia, and the organization grew slowly from 1905 to 1916. The beginning of the use of concrete for pavements about 1910 created a great opportunity for service. It was realized that the use of portland cement would increase only with popular understanding of its possibilities. Intelligent and purely commercial self-interest pointed to a policy of public education regarding the proper use of concrete as the surest means of extending the market for cement. There was much that was known about the fundamentals of good concrete, but there was still more unknown. Consequently the Association set to work to tell the public what was known about good concrete, to find out about those things which were unknown, and to tell the public of other facts as they became established.

In 1916 the name of the organization was changed to Portland Cement Association. The general offices were moved from Philadelphia to Chicago, to obtain the advantage of a central location for a truly national organization, and district offices were established in twelve cities, each in charge of an engineer skilled in concrete construction. Each of these district offices had a staff of field engineers who traveled in assigned territories calling on engineers, architects, contractors or any one who might be interested in concrete construction of any kind. This form of field organization is in use today. These field engineers give direct assistance in design and construction problems involving concrete, and the field staff is supplemented by a staff of engineers in the general office at Chicago, prepared to render consulting service on matters which could not be handled directly by the men in the field or by the district offices. Since 1916 the number of district offices has grown to twenty-four, one of which is located in Vancouver, B. C.

The main office at Chicago, as well as the various district offices, is divided into groups, each in charge of a special field of educational promotion. Agriculture, building construction in its broadest sense, sanitation, highway engineering are all reduced to terms of concrete.

The Structural Materials Laboratory

Probably the most important part of the whole educational scheme is the Structural Materials Research Laboratory operated jointly and in co-operation with the Lewis Institute of Chicago. Here a corps of technically trained men are engaged in research work in the various uses of cement and concrete. Considerably more than 100,000 chemical and physical tests have been made in this laboratory since 1916, and the sc purpose of this work is to determine how best to u concrete as well as how not to use it.

In spite of the fact that the Association is now years old and during all that time has been absorbi knowledge on the use of concrete, within the last sev or eight years more has been learned about how use it than was known in all the years before. Un comparatively recent times nothing was known of t effect which clay and other impurities in concrete mig have upon the finished structure. Studies were ma in the association laboratory on the size and gradi of aggregates, the use of different types of aggregat the effect of various impurities in the aggregate, t incorporation of various powdered admixtures in po land cement such as coloring matter and hydrated lin There was also much experimentation on the effect impure mixing water containing impurities due to i dustrial waste, etc. These studies were necessary order that cement should not be blamed for troul really caused by poor workmanship or impurities in t aggregate or water. This research work has in its sometimes become promotional in character, as will noticed in the following incident:

The Imperial Valley of California is now building concrete road. At the quarry where aggregates we being obtained for the concrete used in this paveme methods employed in screening and crushing stone f the concrete mixture caused a waste of 35 per cent the materials taken from the quarry. One of the fi engineers who was watching the progress of this wo suggested a change in the methods of screening ma rials based on laboratory tests. This step, he believ would considerably reduce the waste of materials. H suggestion was adopted with the result that the wa was cut down to 15 per cent. On this particular job cut the cost of stone from $1 a ton to 42 cents a ton a saved $30,000 on the job. This made it possible f the community to build an extra mile of concrete ro furnishing an outlet for more cement.

Co-operative Work Undertaken by the Association

Among the various classes of educational work c ried on are lectures before agricultural colleges, far ers' institutes, engineering colleges and universiti co-operation with county agents, architects, enginee contractors, building commissioners, revision of bui ing codes, establishment of simple courses in the u of concrete in vocational schools.

Portland Cement Association engineers act in advisory, consulting or inspecting capacity on ma pieces of field construction. Practical demonstratio are given on a motor truck with complete concreti equipment traveling throughout various parts of t country.

Many men have been helped to enter the contracti field, specializing in concrete construction. Throu educational work there has been promoted a high standard for buildings in many cities, and this work being continued everywhere aid is asked. The res of this should ultimately be expressed in economies construction, more fire-resistant construction and c sequent reduction of national fire losses.

Several million educational-informational bookl were distributed last year. These discussed the adv tages of the use of cement in the form of concr construction in many fields. "Concrete on the Da

Farm," "Concrete on the Hog Farm," "Concrete Around the Home" are typical titles of these booklets. Booklets or series of booklets devoted strictly to concrete construction in specialized structural fields are kept available. These booklets are revised by the incorporation of the latest information disclosed by study, research or experience and kept up to date.

Motion Pictures of the Industry

The Association uses motion picture films extensively. There is a film showing the process of manufacture of portland cement. It is designed to develop the idea that a sack of cement represents the combined cost of many operations, one of which, for example, is the use of 50 lb. of coal.

The advantages of paved barnyards are displayed through the medium of animated cartoon films circulated in rural communities. Many reports have been received showing that after a local cement dealer had displayed an animated cartoon film in his community he sold within a week or ten days cement for several concrete feeding floors. The Portland Cement Association has no connection with cement dealers except to aid them in developing the cement market by placing at their disposal motion picture films or other educational matter which they may wish to use.

Several Vital Policies

The most important of the policies that have guided the Association from its start was that of excluding rigidly from its activities any matters relating to the sale or distribution of portland cement. Association employees were told that their mission was to create an increased market for cement by helping the public to make good concrete economically, and to give assistance in the planning of concrete improvements so that such structures would best fulfill their intended purpose.

Chicago, Ill.

Elimination of Borates from American Potash*

The Story of the Steps Taken by Producers to Eliminate this Objectionable Impurity from Domestic Fertilizer as Told by the Bureau of Soils

By William H. Ross and William Hazen

THE principal borax or sodium borate deposits in the United States occur at Searles, Borax and Hachinhama Lakes, Calif., and at Rhodes Marsh, Nevada. These lakes are all of the playa type and contain a concentrated brine in association with crystal salts. Crystals of borax ($Na_2B_4O_7.10H_2O$) are found associated with the other salts at each of these lakes, but owing to its relatively low concentration in the original lake water the greater part of the borax still remains dissolved in the brine of the lakes.

Borax may also be obtained commercially from other borate minerals, the most important of which are colemanite, ulexite and howlite.

Colemanite is a hydrated calcium borate, having the composition $Ca_2B_6O_{11}.5H_2O$. It crystallizes in clear glassy monoclinic crystals which are very easily distinguished from the other borates in that they decrepitate on heating and fall to a powder. Colemanite is now the most important source of boric acid and the borates of commerce. The powdered mineral is somewhat soluble in water and is readily soluble in weak acids.

Ulexite is also a hydrated mineral, the composition of which is represented by the formula $NaCaB_5O_9.8H_2O$. It occurs in aggregates of soft acicular crystals, popularly called "cotton balls." It may be fused in a gas flame to which it gives a yellow color. It is readily soluble in acids and is decomposed by hot water.

Howlite is a borosilicate of calcium, $H_5Ca_2B_5SiO_{14}$. It occurs either as friable masses of monoclinic crystals, or as hard porcelain masses. It fuses in a flame, giving it a green color. Howlite is soluble in acids, but much less soluble in water than either colemanite or ulexite.

These minerals are more widely spread than the borax deposits, and are found in San Bernardino, Inyo, Lake and Los Angeles Counties, Calif.; in Clark, Churchill, and Esmeraldo Counties, Nevada; and in Curry, Harney, and Lake Counties, Oregon. They are found associated with borax at Borax Lake, Rhodes Marsh and other places, but sodium borate and tetraborate (borax) are the only borates known to occur at Searles Lake. The deposit at Searles Lake also differs from any of the other deposits mentioned in that the brine is used as a commercial source of potash, as well as of borax. The brine of this lake is a saturated mother liquor, which remained after the crystal salts were formed by the natural concentration of the water from the ancient lake that occupied this basin. The brine is therefore richer than the crystals in such soluble materials as potassium chloride and borax, which occurred in relatively low concentration in the water of the original lake. Analysis of samples of brine taken from various parts of the lake and at different depths show a close uniformity in composition. The composition of an average sample is given in Table I.

TABLE I—CHEMICAL COMPOSITION OF SALTS DISSOLVED IN THE BRINE OF SEARLES LAKE

Total Anhydrous Salts in Brine is 32.85 Per Cent

Constituents	Per Cent of Anhydrous Salts
Sodium, Na	33.57
Potassium, K	6.06
Lithium, Li	0.01
Barium, Ba	none
Magnesium, Mg	trace
Calcium, Ca	none
Alumina, Al_2O_3	0.012
Iron Oxide, Fe_2O_3	0.003
Copper, Cu	none
Manganese, Mn	none
Silica, SiO_2	0.023
Chlorine, Cl	37.02
Bromine, Br	0.094
Iodine, I	0.004
Sulphate, SO_4	12.96
Carbonate, CO_3	6.70
Phosphate, PO_4	0.30
Arsenic trioxide, As_2O_3	0.083
Tetraborate, B_4O_7	3.00
Total	99.839

*Published by permission of the Secretary of Agriculture.

The relation between the potassium chloride and borax in the brine is shown in Table II. For comparison there are also given the mean of numerous results obtained for these salts by the Geological Survey[1] in the analysis of samples taken from different parts of the lake.

TABLE II—POTASSIUM CHLORIDE AND BORAX IN THE BRINE OF SEARLES LAKE

Salt	Found by Bureau of Soils Per Cent	Found by Geological Survey Per Cent
Potassium chloride, KCl	3.82	4.02
Borax, $Na_2B_4O_7.10H_2O$	2.40	2.07
Anhydrous borax, $Na_2B_4O_7$	1.27	1.08

Table II shows that the maximum quantity of borax that can occur in the potassium chloride prepared from the brine of Searles Lake is in the neighborhood of 25 per cent if the greater part of the potash is recovered with the borax.

Borate Content of Potash from Searles Lake

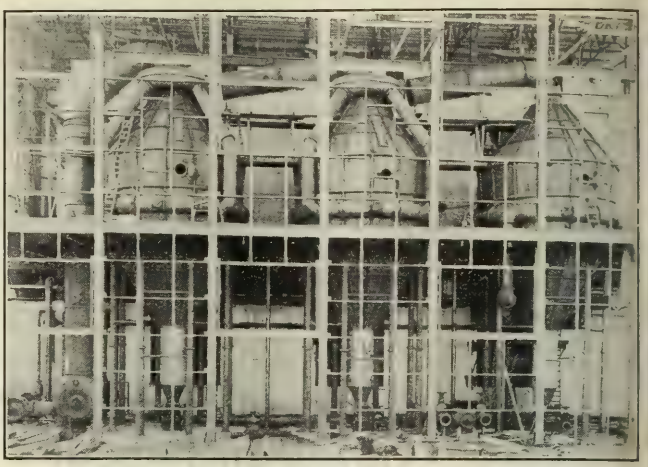
The original process used at Searles Lake for the recovery of potash consisted simply of evaporation and crystallization. The brine was first evaporated to less than half its volume and the solids which separated out from the hot solution, consisting largely of sodium chloride, sodium sulphate, and sodium carbonate were washed back into the lake by a stream of water. The remaining liquor was then run into crystallizing vats and allowed to cool to separate out the potash. The mother liquor from this crystallization was returned to the evaporators to be mixed with fresh brine. The range in the composition of the first crude potash salts produced at Searles Lake is given by the U. S. Geological Survey[2] as follows:

Potassium chloride	60 to 70 per cent
Sodium chloride	5 to 10 per cent
Sodium sulphate	0.5 to 1.5 per cent
Sodium carbonate	1 to 3 per cent
Anhydrous borax	4 to 14 per cent

The first commercial shipments of potash from Searles Lake were made in 1916. During this year a total of 40 shipments were made which were increased to 295 in 1917 and to 376 in 1918. The borax in these shipments showed a wide variation, ranging from less than 1 per cent to a maximum of about 20 per cent.

Crop Injury Due to Presence of Borax in Fertilizer

During the summer of 1919, the attention of the Department of Agriculture was directed to injury to crops by the use of fertilizers. The injury was widespread and serious, especially to the tobacco and cotton crops of the eastern districts of North and South Carolina and to the potato crop of Maine. Several investigators were sent to the regions most affected to study the cause of the injury.[3] Practically all the evidence collected which was later confirmed by field experiments,[4] pointed to the use of fertilizers of potash salts containing borates as the primary cause of the damage to crops. It was observed that the borate content of such mixed fertilizers was roughly proportional to the potash present and that the higher the borate content the greater the injury to crops. The source of the potash salts used in these fertilizers was traced to the salt deposit at Searles Lake.



EVAPORATORS AT TRONA CORPORATION PLANT AT SEARLES LAKE

Analyses of numerous fertilizers reputed to have caused injury to crops showed a borate content varying from 0.75 to 2.0 per cent in terms of anhydrous borax. Considerable difficulty was at first experienced in determining borates in mixed fertilizers by the usual methods of analysis, owing to the interfering action of the soluble organic matter of the fertilizer. However, a modification of the Thompson method was soon developed by the Department[5] which eliminated this difficulty while J. M. Bartlett[6] of the Maine Experiment Station made a satisfactory modification of the Gladding distillation method. The former method gives water-soluble borates in fertilizers and the latter acid-soluble borates. The agreement in the analyses of numerous fertilizers by both methods shows that these fertilizers at least contained only water-soluble borates. This is to be expected inasmuch as the potash salts used in fertilizers are mainly water-soluble and even if there had been added some of the "insoluble" mineral borates, the latter would be rendered soluble by the acid reaction of the mixed fertilizer.

Order Issued by the Department of Agriculture Limiting Borax Content of Fertilizers

As soon as injury to crops by borate-bearing fertilizers was established, the Secretary of Agriculture issued an order under authority of the Control Act of Aug. 10, 1917, which placed such restrictions on the use of fertilizers and fertilizer materials containing borates as would guarantee the use of an application amounting to the equivalent of not more than 2 pounds of anhydrous borax per acre.

GENERAL VIEW OF POTASH PLANT, AMERICAN TRONA CORPORATION

The regulation as applied to mixed fertilizers specified that "hereafter no licensee handling or dealing in fertilizers or fertilizer ingredients shall sell for application to the soil any mixed fertilizer which contains more than 0.1 of 1 per cent of borates expressed as anhydrous borax unless the container thereof be marked, tagged, branded, or labeled so as to show plainly and conspicuously as part of the analysis the percentage of borax present."

The order as applied to potash salts forbade the sale direct to farmers as straight goods, or to any broker or other person for use by farmers as straight goods, potash salts containing borates equivalent to more than 0.5 of 1 per cent of anhydrous borax.

In compliance with this regulation, immediate steps were taken at once by potash producers and fertilizer manufacturers to insure the elimination of borates from all the raw materials entering into the manufacture of fertilizers. Their efforts in this direction have met with such success that since 1919 no mixed fertilizer is known to have been placed on the market with a borate content in excess of the limit specified in the regulation.

Diminished Borax Content of Searles Lake Potash Under Revised Process

On Sept. 5, 1919, an inspection was made of the plant of the American Trona Corp. at Searles Lake, by Dr. J. W. Turrentine of this Bureau. The investigation that was made at that time showed that marked progress had already been made in the refinement of the potash salts. It was found that when the original process was modified so as to bring about a rapid, rather than a normal cooling of the mother liquor from the precipitated sodium salts, the potassium chloride crystallized out as before, but the borax remained in solution. The sludge of crystals thus formed was filtered off and washed in the centrifugals with water for the removal of the retained mother liquor which contained the borax.

Table III gives the composition of samples of the original product and also of material collected at different steps in the process as operated at the time of the inspection in 1919.

At the time the samples listed in Table III were analyzed, an examination was also made of a large number of fertilizer materials from other mineral deposits. A summary of the results obtained is given in Table IV.

The results given in Tables III and IV show that it is commercially feasible to produce a potash product from Searles Lake or any other mineral deposit in this country having a borate content well within the limits set by this Department for that occurring in straight goods to be applied directly to the soil and that the product compares favorably as regards its borate content with the ordinary sodium nitrate imported from Chile.

TABLE III—VARIATION OF BORAX CONTENT OF POTASH SALTS PRODUCED AT SEARLES LAKE BY OLD AND BY THE MODIFIED PROCESSES

No. of Sample	Potash K_2O Per Cent	Anhydrous Borax $Na_2B_4O_7$ Per Cent	Anhydrous Borax Per Unit (20 Lb) of K_2O Pounds
1	31.62	18.14	11.48
2	46.91	2.43	1.03
3	52.57	0.80	0.30
4	52.03	2.61	1.00
5	40.93	0.86	0.42
6	56.26	1.16	0.41
7	54.90	0.28	0.10
8	55.29	0.41	0.14
9	53.23	0.59	0.22
10	50.56	0.20	0.08
11	43.42	0.15	0.07

1. Low-grade potassium chloride prepared by the original process.
2. Medium-grade vat salts prepared by the original process.
3. Potash salts as delivered by filter presses, and before drying and washing in centrifugal driers.
4. Main filter salts unwashed. These are salts as delivered by filter presses without washing in centrifugals.
5. Same as sample 4 but from another section of the pile.
6. Same as sample 4 but from a third section of the pile.
7. Potash shipping salts taken directly from centrifugal driers. The salts represented by this sample were washed on the driers with a small amount of water to remove the mother liquor containing the borax.
8. No. 1 grade filter salts washed with so-called sump solution. From a lot containing 392 tons.
9. No. 1 washed filter salts from another pile of the same grade as that represented by sample 8.
10. No. 2 grade centrifuged filter salts washed with sump solution. From a lot containing 800 tons.
11. No. 2 grade potassium chloride washed with water and which with sample 10 represents the degree to which it is practical to eliminate borax by the modified process.

TABLE IV—BORAX IN MISCELLANEOUS FERTILIZER MATERIALS

Material	Anhydrous Borax Per Cent
Potash salts from Nebraska lakes	0.07 to 0.15
Potassium sulphate from alunite	0.00
German kainite	0.00
German manure salts	0.00
Alsatian manure salts	0.00
Refined potassium chloride from Salduro Marsh	0.00
Refined potassium chloride from Deep Springs Valley, Calif.	0.00
Sodium nitrate from Chile	0.05 to 0.83
High potash nitrate from Chile	0.15 to 3.95

At the request of the American Trona Corporation, a second inspection was made of their plant at Searles Lake, Cal., on April 30, 1922, by Dr. J. W. Turrentine of this Bureau. About 5,800 tons of potash salts were found in storage in the warehouses of the company. Some of this, about 3,000 tons, had been manufactured in the fall of 1920, and the remainder approximately in the spring of 1921. About 300 tons were produced

since the reopening of the plant, 10 days previously. The same general process was being used of separating the potash and borax by rapid cooling with refrigerating brines, as was used in 1919, but certain improved modifications in equipment have been installed. Samples were collected as in 1919, the composition of which are given in Table V.

TABLE V—COMPOSITION OF POTASH SALTS PRODUCED AT SEARLES LAKE DURING 1920 TO 1922

No. of Sample	Potash K_2O Per Cent	Anhydrous Borax $Na_2B_4O_7$ Per Cent	Anhydrous Borax Per Unit (20 Lb.) of K_2O Pounds
1	60.75	0.50	0.16
2	58.72	0.24	0.08
3	57.94	0.39	0.13
4	58.63	0.30	0.10
5	57.64	0.46	0.16
6	61.15	0.36	0.11
7	61.50	0.25	0.08
8	61.80	0.25	0.08
9	59.55	0.27	0.09

1. Potassium chloride from a vertical 5-ft. section of 3,000 tons potash salts manufactured in the fall of 1920.
2. Potassium chloride from loading floor. A part of material manufactured in spring of 1921.
3. Sample of potassium chloride through vertical 5-ft. section near south end of 3,000-ton pile, manufactured during the spring of 1921.
4. Same as sample 3 taken from entire working face 15x50 ft. cross-section of the south end of pile.
5. Same as sample 3 taken from 5-ft. vertical section, middle of pile.
6. Sample from centrifugals as delivered into box for transportation to storage.
7. Sample from box already filled just before being transferred to warehouse.
8. Sample of 300 tons of new potash produced since reopening of plant.
9. Sample of product being delivered by centrifugals, April 30, 1922.

The results in Table V confirm the conclusions arrived at from the data given in Table III, that it is commercially feasible to produce a high grade potash salt from the brine of Searles Lake, having a borate content well within the limits specified by this Department.

This Bureau has followed closely the course of American potash production, not only with a view to assist in establishing commercial sources of potash but also in maintaining a quality of material that would be suitable for use as fertilizer without fear of injury to crops. Borax has been the only substance of a deleterious nature discovered in American potash and the quality of the materials produced during the period from 1919 to 1922 show that the producers have met the requirements of the Department and that under the present method of producing potash at Searles Lake there exists no longer any danger of deleterious effec from the presence of borax.

Potassium chloride and borax ($Na_2B_4O_7$) occur in t brine of Searles Lake in the proportions of about 3.3 1. The maximum quantity of borax that can occur the potassium chloride from this source is therefore the neighborhood of 25 per cent. The first commerci shipments of potash from Searles Lake contained maximum of about 20 per cent of borax which wh used in fertilizers resulted in serious injury to cro By modifying the original process so as to bring abo a rapid rather than a normal cooling of the moth liquors containing the potash salts a high grade pot sium chloride is now being prepared. This contai less than the equivalent of 0.5 per cent anhydrous bor which compares favorably with the content of borax sodium nitrate, a nitrogen carrier long used in fertil ing the crops of this country. Borax has been the on deleterious substance found in American potash and t quality of the materials produced during 1919 to 19 shows that the producers have met the requiremen of the U. S. Department of Agriculture and that the no longer exists the former danger to crops from t presence of borax in fertilizers.

Department of Agriculture,
Washington, D. C.

Pure Iron-Carbon-Manganese Alloys

As a continuation of the Bureau of Standards' pr vious work on the preparation and properties of pu iron and iron-carbon alloys, there has just been co pleted a series of alloys of electrolytic iron, carbon a manganese, so chosen as to show the effect on t mechanical properties of pure iron of additions carbon up to 1.2 per cent, of manganese up to 1.5 p cent, and of carbon and manganese together in varyi relative proportions up to the same limits. All the alloys were prepared *in vacuo* in order to eliminate far as possible any effects from gases and in ord to obtain sound material without the use of any deo idizing additions. The ingots of this series were roll to flat bars, tensile test specimens cut from them a tested in the fully annealed state. The data from the will soon be available as a Bureau publication. Th same investigation is being extended to cover simp heat treatments of selected vacuum fuse iron-carbo manganese alloys.

SEARLES LAKE, CAL.

Resistance to Corrosion Of Various Types of Chromium Steels

Several Pure Chromium Steels, in Cast, Forged and Heat-Treated Conditions, Were Observed During Immersion in Dilute HCl and in Aërated Distilled Water—Relative Resistance to Attack Is Entirely Different in the Two Series

By Henry S. Rawdon and Alexander I. Krynitsky
Physicist and Associate Physicist (Metallography), Bureau of Standards.

LACK of adequate information on this subject in the technical literature together with the numerous requests for information along this line which have been received has led to the publication of the results of these preliminary experiments which were initially undertaken at the request of one of the prominent American steel men. As the work progressed it appeared desirable to test several other materials besides the chromium steels for purposes of comparison (series 21 to 24 of Table I), one of these being a chromium-nickel steel submitted by the manufacturers for the purpose. The tests were carried out in the endeavor to show the relative corrodibility of the various types of steel rather than to study any one material in detail. Hence it was necessary to limit the number of corroding conditions used.

Materials Investigated

The chromium steels investigated (Table I) were prepared by L. Jordan, of the Bureau of Standards, the fusion being made in the high-frequency induction furnace. Only small ingots averaging about 1 lb. (550 grams) each could be made. Armco iron was used as the base material; this contained approximately 0.02 per cent sulphur and 0.015 per cent carbon, with other impurities negligible in amount. To this was added the requisite amount of chromium in the form of ferrochromium containing approximately 60 per cent chromium and 0.25 per cent carbon. For the steels of a relatively high carbon content, the carbon was added in the form of an iron-carbon alloy prepared with electrolytic iron as a base and containing 4.4 per cent carbon. An addition of a small amount of manganese was made to all the alloys and silicon to a portion of the series in order to obtain sound ingots and to render them forgeable.

After the ends had been cropped, the ingots of chromium steel were heated to a temperature slightly less than 1,000 deg. C. and pressed into plates approximately ½ in. in thickness. All of the steels after forging were annealed at 750 deg. C. and most of them received an additional heat-treatment before the corrosion test, as indicated in the subsequent tables in which the results of corrosion tests are summarized. Portions of the cropped ends of the ingots of the cast metal were also tested as being representative of the material in the cast state. The iron and other steels investigated were in the forged condition; samples of the pure iron in the cast condition were also used.

The specimens used for the test were small pieces of a rectangular prismatic shape, the surfaces of which were carefully ground so that their dimensions could be readily measured by means of a micrometer. The effect of surface finish—that is, rough grinding versus polishing—was also noted.

TABLE I—COMPOSITION OF ALLOYS USED IN CORROSION TESTS

Series	Character of Material	Important Elements (Per Cent)					
		Carbon	Chromium	Manganese	Silicon	Sulphur	Nickel
1	Chromium steel	0.45	12.42	0.27	Not determined. Silicon was not used in preparation of the alloys.	— Not determined —	Not determined, but not present in more than traces.

23	Invar	0.08	Not detected	0.45	0.18	.....	36.13
24	High-nickel chromium steel	0.32	7.68	0.68	1.03	0.20	20.12 Co 0.10 Cu 0.095 P 0.026

Nature of Test

Two types of tests were used, one for determining the resistance of the materials to corrosive attack by acid, the second one being a simulated "weather" test. Since the purpose of the tests was to demonstrate the relative resistance of a series of alloys of different compositions rather than the behavior of one or two compositions under a series of different conditions, only one acid, dilute hydrochloric, was used. This acid was chosen since its action upon chromium steels is relatively more severe than that of most other acids. The attack is also less complicated in character than is the case with strongly oxidizing acids such as nitric. Results are expressed as the loss in weight in milligrams per square centimeter of surface per day.

The necessity for using either a considerable excess of acid during the acid-immersion test or a rather short period in order to obtain a true measure of the relative solubility of the materials became evident early in the experiments. As the concentration of acid decreased and that of the "corrosion products" increased, the rate of attack, as indicated by the evolution of the gas, was found to diminish noticeably, so that specimens of the same size differing widely in composition were found to lose approximately the same amount if

Published by permission of the Director of the Bureau of Standards.

the immersion was prolonged enough, although the solutions in which they were immersed showed a strong acid reaction at the completion of the test.[1]

The "weather" test consisted in the exposure of specimens suspended so as to be immersed in distilled water just beneath the surface, the uncovered dish of water being kept near an opened window so that a supply of fresh air at all times was assured. The time required for the appearance of rust for tarnishing of the surface was taken as an approximate measure of the resistance of the material to "weathering" conditions and the specimens could be arranged in order on this basis. A few samples which purposely had not been thoroughly ground free from oxide scale were also tested in this manner to show to what extent the presence of scale affects the rate of corrosion.

In all the tests the samples were suspended by means of silk thread in the water or acid solution used so as to hang freely and not to be in contact with the glass vessel, which might possibly affect somewhat the rate of attack. The identification numbers were not stamped on the material itself, since this might have some effect upon the attack, but were written on a wooden identification tag.

Acid Corrosion

The effect of a hardening treatment upon the rate of attack of typical chromium steels is well shown by series 1 to 6 inclusive in Table II. The apparently anomalous results of series 1 may have resulted from the fact that the quenching temperature used was somewhat low for the composition of this particular specimen. All of the other samples showed a marked decrease in the loss in acid when in the hardened state. The specimens of highest carbon content, for example, 3 and 6, showed the greatest decrease.

TABLE II—RESULTS OF ACID-CORROSION TESTS ON FORGED BARS

Series	Carbon and Chromium, Per Cent	Heat Treatment Received	Character of Surface	Immersion In *N*/2 HCl	Loss in Wt. Per Sq.Cm. Per Day, Mg.

19	14	C, 0.29; Cr, 13.70	77.7
20	9	C, 0.38; Cr, 12.10	84.5

Tests also indicate that, in general, the cast alloys are more resistant to hydrochloric acid attack than are the same materials after being forged.

The relative order of resistance to acid corrosion of the various alloys is best known by comparison of the specimens in the same physical condition. In Table III have been grouped the data which relate to the forged alloys in the annealed state.

"Weathering" Test

The behavior of the materials when exposed under ordinary conditions of atmospheric corrosion was determined by immersing the steels in distilled water, just below the surface, and exposing the uncovered dish to the free air. By observing the change in the appearance of the previously polished surface of the specimens, the period necessary for the appearance of rust spots, the relative extent of the rusted areas after a certain definite period and the change in weight of the specimens, it was possible to arrange the various steels in certain groups with respect to their corrodibility.

In determining the change in weight, the surface was cleaned by rubbing with the finger so as to remove any loosely adherent rust. Most of the specimens showed a very slight decrease in weight, thus indicating that the rust formed under the conditions used was not very firmly adherent.

In Table IV are summarized the conclusions reached concerning the relative resistance of the various steels to "weathering." In most of the chromium steels the corrosive attack was confined to small areas or pits, a fact which suggests that the average chemical composition of the material as determined by analysis is not the only factor which determines the behavior of the steels with respect to corrosion. Since the attack in most cases did not result in a uniform film over the surface, but was restricted to small isolated areas, the changes in weight noted do not appear of as much significance as would be the case otherwise and hence have not been included.

Discussion and Summary

There will be noted in the foregoing tables, particularly in Table IV, in which are summarized the results of the "weather" tests, some results which are very difficult if not impossible for one to explain on the basis of composition alone. The classification which has been given should be regarded as a very loose one, indicating only the general behavior which may be expected of the

various alloys. However, there are some very definite conclusions which the results of the investigation appear to warrant.

1. *Acid Corrosion.*—A comparison of the results of Table III with those of Table IV shows that the relative resistance of a steel to the hydrochloric acid test is not necessarily a criterion of its behavior in atmospheric corrosion. Pure iron and the steels of low chromium content were found to be much more resistant to attack by hydrochloric acid than those containing considerable chromium. When corroded by water and air the general order of resistance was reversed. It may be concluded, then, that the addition of chromium to iron and steel increases the rate of attack by hydrochloric acid and perhaps by others, although this statement may be modified somewhat according to the condition of the steel with respect to the heat-treatment it has received. Specimens which had been hardened by suitable heat-treatment were found to be considerably more resistant to acid attack than samples of the same composition in the annealed state. The addition of nickel is much more effective in reducing the intensity of the attack by hydrochloric acid than is chromium. The steels containing a considerable amount of nickel were found to be the most resistant to acid of all those which were used.

Specimens having a polished surface were found, almost invariably, to show a smaller loss in acid than those which were roughly ground. This difference may be only apparent, however. Although the measured surface of the two specimens may appear to be exactly the same, the one with a "ground" finish has a slightly greater area exposed on account of the minute grooves and ridges which make up the surface than has the polished specimen.

TABLE IV—RELATIVE RESISTANCE OF THE STEELS TO CORROSION IN DISTILLED WATER

Order	Approximate Period Before Rust Was Noted	Approximate Area Which Had Lost Luster or Was Rusted After 19 Days	Series of Steels
1	150 days (no rust)	.....	17, 17 (*a*)
2	63 days	.....	9
3	22 days	.....	24
4	13 days	Few very small specks	2 (*H*)
5	7 days	Larger specks, approximating $\frac{1}{8}$ to $\frac{1}{4}$ of surface area	1 (*H*), 3 (*H*)
6	3 days	Ditto	1 (*A*), 9 (*a*), 13, 14, 15 (*a*), 19 (*a*), 17 (*a*), (*b*)
7	18 hours (trace of rust)	Ditto	7, 7 (*a*), 7 (*b*), 7 (*b*) (*a*), 9 (*b*) (*a*), 13, 14 (*a*), 15, 15 (*a*), 17 (*b*), 19, 19 (*b*), 19 (*b*) (*a*)
8	18 hours (trace of rust)	About $\frac{1}{2}$ surface	8, 8 (*a*), 8 (*b*), 13 (*a*), 13 (*b*)
9	18 hours (small amt. of rust)	Small portion of approximately $\frac{1}{2}$ area retained its luster	2 (*A*), 3 (*A*), 4 (*A*), 4 (*H*), 5 (*H*), 6 (*A*), 6 (*H*), 18, 18 (*a*)
10	18 hours (small amt. of rust)	No luster remained. Surface was etched and has a mottled appearance	5 (*A*), 18 (*b*), 18 (*b*) (*a*), 20, 20 (*a*), 20 (*b*) (*a*), 20 (*b*)
11	18 hours (considerable amount of deposit)	No luster remained on surface	21, 22 22 (*a*)

(*a*) Cast, annealed at 750 deg. C. reheated to 500 deg. C. after machining.
(*b*) Specimens had adhering specks of oxide scale on the surface, otherwise they were the same as others of the series.
(*A*) Annealed at 750 deg. C. after forging, annealed at 750 deg. C. after machining.
(*H*) Heat-treated; annealed 750 deg. C., after forging, water-quenched from 1,000 deg. C. (except 1 and 4, 813 deg. C.), tempered 180 deg. C.
Other specimens (except 21 and 24) were annealed 750 deg. C. after forging at approximately 1,000 deg. C. reheated to 500 deg. C. after machining. Specimens 21 and 24 were cut from a forged bar and annealed at 500 deg. C.

2. *Atmospheric Corrosion.*—For resisting corrosion by water and air a considerable amount of chromium in a steel is necessary. The alloys of this general type were found much more resistant than were those of low chromium content. These latter steels, however, were found much more resistant than the simple carbon steel or "pure" iron. Hardening the chromium steel by heat-treatment was found to have a similar effect in retarding corrosion by water and air as in the acid tests. This was true in particular for the steels of high chromium content. The specimens lower in chromium showed very little difference in resistance to corrosive attack regardless of their condition with respect to heat-treatment. Adhering patches of oxide scale upon the surface were found to have a very noticeable effect in accelerating the rate of attack of the chromium steels.

The alloy containing a high percentage of nickel as well as chromium which was found to be attacked the least by acid also proved very resistant to atmospheric corrosion. It was much better than most of the chromium steels used, although it was far surpassed by certain of the high chromium materials tested.

It was noted in most cases that the corrosion of the chromium steels consisted in an attack at small isolated spots rather than in a general tarnishing and coating of the surface. This, in view of the fact that adhering particles of oxide scale accelerated the corrosive attack of a steel to a very marked degree, suggests that the presence of inclusions or other defects within the material may be responsible in large measure for the character of the surface pattern resulting from the corrosive attack of these steels.

It will be noted that the high-chromium steel which proved to be superior to all the others in its resistance to "weather" corrosion contained a considerable amount of silicon. However, whether this fact is of real significance is a matter of conjecture so far as the present tests indicate. Specimens 14 and 15, which also contained considerable silicon, though less than specimen 17, did not show any unusual corrosion-resisting properties. The difference in carbon and manganese contents in these specimens may be of pronounced significance, however, in this respect.

In the choice of a "non-corrodible" steel, the character of the service will be the criterion which determines which is the proper type to use. For example, it is evident from the preceding results that as a material for which the resistance to severe acid attack, such as hydrochloric, is the principal requirement, a high-chromium steel would be the least suitable of all the materials used in this investigation. In most cases, however, the service which any material will undergo is a combination of various factors. Thus, for example, cutlery steel must withstand both acid and atmospheric corrosion as well as possess certain necessary mechanical properties, "forgeability," hardness, etc. No single type of non-corrodible steel appears to be suitable for each and every purpose which may arise.

Competition of Indian Mica

A feature that renders it almost imperative for the America mica producer to develop more efficient methods is the competition with cheap Indian labor, acccording to Oliver Bowles, mineral technologist of the Bureau of Mines. Labor costs in India are exceedingly low and it is difficult, therefore, for Americans with their higher standards of living and consequently higher wages, to compete successfully with the Indian product. Mining methods in India are very crude and laborious and it is only by taking advantage of superior methods that America can hope to succeed in establishing a flourishing mica industry.

Maturing Flour—I

Summary of Present Knowledge Regarding the Action of Chlorine on Flour—Maturing Effect—Baking-Quality Stabilized as Result of Arresting Enzyme Activity So That the Acidity May Be Maintained at the Optimum Point

By Frederick L. Dunlap, Sc.D.
Consulting Chemist, Industrial Appliance Co., Chicago, Ill.

WHILE a large number of methods have been proposed for treating flour in order to improve its color or quality—as is evident from a study of Dr. Morison's résumé of flour-treating methods published recently in *Baking Technology* under the caption "Why Bleached Flour?"—very few of these have been of any particular moment in a practical and operative way and have achieved anything like a commercial success.

So far as practical adoption by millers is concerned, the forerunner of all the methods is what is known as the nitrogen dioxide process. As now conducted, its operation depends on the heat generated by an electric discharge causing some of the oxygen and nitrogen of the air to combine, with the formation of nitric oxide. This substance then takes up oxygen from the air and forms nitrogen dioxide. It is this latter that is the active agent in this process for treating flour.

This method of treating flour with NO_2 is the earliest of the commercial methods used in the United States, and the flour so treated was known as "bleached flour." The method and product produced by such method have been the source of extensive litigation both in this country and in England. Nitrogen dioxide-treated flour was the one which became more or less generally known through government activities, for at that early period it was the sole treated flour on the American market. Published results of experiments both in this country and abroad indicate that flour treated with nitrogen dioxide, while very much whiter than before treatment, is not materially affected in its baking quality.

While the term "bleach" from a dictionary standpoint does mean "to make white," yet with this historical setting, it has come to mean the treatment of a flour whereby such flour is made whiter, but nothing else.

Aging of Flour

Flour when it ages turns whiter and increases in the quantity of acidity. As flour ages, it becomes a better flour, for it produces a larger and better loaf of bread. Freshly milled flours do not produce the best of which they are capable. A great advance was made in the milling art by the introduction of a method for treating flour in the mill, whereby such freshly milled flour at once took on the properties of a properly aged flour, so that the flour could then go to the consumer in condition to render at once its highest baking value.

The aging of flour is not commercially feasible. The cost is against it, for one thing. Another objection, from a commercial standpoint, is the impossibility of following the condition of the aging flour, especially if one wishes to catch it at its peak, for stored flour is constantly varying in its baking capacity, finally reaching an optimum and then beginning to decline. Hence any method which the miller can employ, assuming for the moment that it is unobjectionable from a health standpoint, which will instantly convert a flour to its optimum baking value and then stabilize it, is of great moment to the public.

Maturing of Flour by Chlorine Treatment

This state of affairs is brought about in flour by treating it with chlorine, and the general result is known as "maturing"—*i.e.*, the general effect of "maturing" flour is that which nature produces in aging flour—a whitening effect together with greatly improved baking qualities. It is quite evident that there is a distinction between "bleached" and "matured" flour.

Nature of Coloring Matter in Flour

Whatever the method used to treat flour, if the resultant product is whiter, then it is certain that the yellow coloring matter of the flour has been discharged to a greater or less extent. Not much is known concerning this yellow coloring matter of flour, but in 1912 Dr. G. W. Monier-Williams established its identity with carotin, the yellow coloring matter found in carrots and also in the green portions of plants.[1] While the amount of carotin contained in flour will vary considerably, in no case is it very large, Monier-Williams having found 1.3, 1.4 and 2.0 parts per million in samples of patent flour.

Willstätter and Mieg[2] have shown that carotin is a hydrocarbon, $C_{40}H_{56}$. It forms red crystals of a coppery luster having a melting point of 167.5 to 168 deg. C. With the halogens it forms addition compounds of the type $C_{40}H_{56}I_2$. The relative toxicity of carotin and dichlorcarotin, $C_{40}H_{56}Cl_2$, has been studied by Wells and Hedenburg,[3] who reached the following conclusion: "Evidently carotin possesses no considerable toxicity if any, and chlorination does not make it demonstrably toxic. The quantities of carotin used in these experiments are enormous in comparison to the amounts that could be obtained from any food, even carrots. The larger doses used, 0.2 g., are as much as is contained in 200 kg. of flour. . . ."

Oxidation of Carotin Causes Whitening of Flour

Willstätter and Mieg say that carotin absorbs oxygen and is thereby completely decolorized. The oxidation goes on rapidly even in the dark and in the absence of moisture. In one set of experiments Monier-Williams exposed 0.1 to 0.2 g. samples of carotin to the air for two months in both the city of London and in Widnes.

[1] Report to the Local Government Board by Dr. G. W. Monier-Williams, on the nature of the coloring matter of flour and its relation to processes of natural and artificial bleaching.
[2] *Ann.*, vol. 355, p. 1 (1907).
[3] *J. Biol. Chem.*, vol. 27, p. 213 (1916).

se increased in weight about 30 per cent and became ter in color—i.e., a light orange red. The increase weight was at first very slow, being scarcely per- tible for six days, but after this it became fairly id. In one sample, equilibrium was reached in 75 s with 32.3 per cent "oxygen absorbed." This cor- ponds fairly well with the 34.3 per cent oxygen orption obtained by Willstätter and Mieg, in treating otin with pure oxygen.

The Role Played By Nitrites in Whitening Flour

An interesting observation of Monier-Williams on se exposed samples is that the smallest trace of rite could not be detected in any of these carotin nples by the Griess-Ilosvay test, even after the otin had been submitted to long exposure to the osphere, nor could any nitrogen be found by the ldahl method on a 0.2-g. sample using salicylic acid sodium thiosulphate. He remarks that "it is only sonable to assume that the natural aging of flour similar process." It is reasonable to assume that nier-Williams means that the whitening of flour ough aging is a phenomenon due to the oxidation of carotin.

He showed that carotin combines or reacts readily h NO_2, and also states that flour exposed to the air es up nitrite-reacting material or such nitrite- cting material is produced within the flour itself. uld not the inference be a fair one from Monier- liams' and Willstätter and Mieg's results, that in likelihood nitrite-reacting material plays little or no t in the whitening of flour on aging, but that oxygen ys the major rôle? Be that as it may, Wesener l Teller state with respect to the use of NO_2 that idently the artificial aging of flour is identical with natural aging which has been going on ever since ite flour was produced."

Action of Chlorine on Flour

So far as the action of gaseous chlorine on flour is cerned, it would seem that the broad principles of h action may be stated by saying that it acts on carotin and unsaturated glycerides, forming addi- n products. We know further, that water and orine react, this reaction being carried on until an ilibrium is established between the HCl and HClO med and the H_2O and Cl. Hypochlorous acid would, course, be readily reduced with the formation of drochloric acid. The equilibrium would then be re- ablished with subsequent reduction of the HClO and on, until the chlorine has been converted into hydro- oric acid. It is the hydrochloric acid which gives increased acidity to flour which is treated with orine, and this increase is capable of control by the ree of treatment.

Baking Quality Stabilized by Maturing

There are also other interesting changes which take ce in flour which has been subjected to this action. ong these is one which acts so as to maintain the lity of the treated flour at a constant point. This stitutes a marked differentiation from untreated r, the acidity of which keeps constantly increasing. smuch as the intensity of the acidity is probably the t important variable in determining the baking ue of any flour, it will be of interest to give an mple of results obtained from a fresh flour and the same flour subjected to treatment with chlorine. The sample in question was a spring wheat:

Flour	Time	Ash, Per Cent	Acidity	Volume, c.c.
Fresh	At once	0.40	0.112	2,060
Matured		0.40	0.151	2,340
Fresh	After 116 days	0.40	0.133	2,300
Matured		0.40	0.151	2,350
Fresh	After 259 days	0.40	0.135	2,390
Matured		0.40	0.151	2,350

From these results it can readily be seen that the fresh flour had nearly reached its optimum in baking capacity, whereas the matured flour remained constant. The greatest change in the baking value of the fresh flour developed after four months of storage, but the baking value continued slowly to increase up to the ninth month and had not yet begun to recede.

On the other hand, a sample of fresh flour in storage gave these results: The volume of the loaf was, when the flour was baked at once, equal to 2,050 c.c. After 117 days this volume had increased to 2,440 c.c.; after 308 days the volume had decreased to 2,250 c.c. The difference in the time it takes a natural flour to age to its optimum value is undoubtedly not only influenced by storage conditions, but by the different blends of wheat from which the flour is produced and by the method of tempering, as well as the manner of milling.

In this connection, it is interesting to note a reference to some, as yet unpublished, work of Bailey and Johnson, which is found in the concluding installment of Dr. Morison's article on "Why Bleached Flour?":[4] "Bailey and Johnson (1922) have studied the effect of chlorine bleaching upon the electrolytic resistance and hydrogen-ion concentration on water extracts of flour. They found that bleaching flour with chlorine increases the specific conductivity, hydrogen-ion concentration, and buffer action of flour extracts in direct ratio to the quantity of chlorine used. These differences apparently do not disappear on storing the flour for some months."

Enzyme Activity Arrested

This stabilizing of the baking quality of a matured flour, which baking quality depends so largely on the hydrogen-ion concentration, is undoubtedly due to the action of the chlorine on the enzymes normal to the wheat berry, whereby their activity is arrested. This raises the question as to what the increase in acidity of a stored flour is due. So far as we now know, the acidity of flour is due to phosphoric acid or its acid salts, and to amino acids; the former are doubtless of more importance from the standpoint of acidity. The source of the phosphoric acid or its acid salts is phytin, which undergoes hydrolytic cleavage through the activity of the enzyme phytase. Proteolytic enzymes would hydrolyze the proteins, with the formation of amino acids as a final cleavage product. Proteolytic enzymes do not all have the capacity to hydrolyze proteids to the extent that amino acids are formed. For example, pepsin causes a hydrolysis of proteids with formation of proteoses and peptones, which are only an intermediate step toward the amino acids.

The arresting of the activity of the enzymes in flour by the action of chlorine is not a serious matter. The enzymes that are present are there for the sole purpose of acting when the wheat berry is utilized to produce its kind. Then these enzymes become necessary to split the contents of the berry into suitable food, for

[4] *Baking Technology*, vol. 1, p. 135 (1922).

nourishment of the growing embryo, until the root system has been established and the young wheat plant can obtain proper food from the soil. In discussing some work of Baker and Hulton,[5] who had carried on experiments to determine the value of the enzymatic constituents of flour as they might effect bread making, Humphries has remarked that "these ferments were there to make the kernel of wheat available as food for the young plant," and that "nature in making wheat was more concerned with the reproduction of its kind than in feeding human beings."

Amount of Chlorine Varies With Nature of Flour

It is not possible to give any exact figures on the amount of gaseous chlorine necessary to add to any flour in order to produce that concentration of hydrogen ions so necessary to develop in the flour its highest baking value. It is somewhere in the neighborhood of 150 parts per million, but it may be more and it may be less. In a comparison of the different grades of flour it is necessary to contend with a greater buffer effect in the lower grades than in the higher, so that the lower grades on this account require a larger amount of chlorine to produce the necessary intensity of acidity. This buffering effect is due probably to phosphates, and possibly to the proteids too, as has been pointed out by Jessen-Hansen, Lüers and others. Recent work of Bailey and Peterson[6] lead them to the view that in the extracts from flours the phosphates may be the principal buffers. They say that "electrometric titration curves show the extracts of high-grade flours to be buffered less than the extracts of lower grades. It consequently requires less acid to bring the hydrogen-ion concentration of a high grade or patent flour dough to the optimum for bread production than is required for a low-grade flour. Possibly some of the difficulties experienced in making satisfactory bread from the lower grade or clear flours may be due to failure to obtain the optimum hydrogen-ion concentration of the dough." They also say: "In view of the decided differences in the buffer action of high-grade or patent, and low-grade or clear flours, it is possible that some of the difficulties experienced in producing satisfactory yeast-leavened bread from the lower grades may be due to failure to obtain the proper hydrogen-ion concentration of the dough. Further experimentation with these lower grades of wheat flour, containing more than 0.60 per cent of ash, should be conducted to ascertain the possibilities in this direction. Since conditions generally are unfavorable to the production of choice bread from clear flour, it is probable that a more careful adjustment, within narrower limits, is necessary than in case of doughs made from patent flour."

Importance of Controlling Hydrogen-Ion Concentration

Within the limits of this paper it is not practical to discuss the splendid experimental work which is being done on flours not only in this country but also abroad. The general trend of all these investigations is toward the utilization of physicochemical methods in studying flour *per se*, as well as gluten. Out of all this work has come some splendid results, and it is to be hoped that the time is not far distant when that most important scientific question of what constitutes the strength of flour will be solved. Whether the answer will be found revolving around the colloid properties of the various flour constituents remains to be seen. Already considerable is known about the effects of varying hydrogen-ion concentration and salts on the imbibition properties of gluten. This affects markedly the physical properties of the dough and the elasticity of the gluten. In order to get best baking results the gluten must have the proper elasticity and the dough the proper viscosity. The intensity of the acidity of the flour or dough is the most important variable in bread making. We know that when we control, in a proper fashion, the hydrogen-ion concentration through the treating of flour with chlorine, we are on substantial scientific grounds. In this fashion we are able to influence the viscosity of the dough until it becomes practically a minimum, at which point the gluten seems to have the proper degree of elasticity. As Bailey and Peterson have said:[7] "Through the proper hydrogen-ion concentration the elasticity of the gluten and the activity of the yeast and of 'rope producing' bacteria are affected in the right direction."

Henderson, Fenn and Cohn,[8] in their study of the "Influence of Electrolytes Upon the Viscosity of Dough," remark that " . . . it is evident that with variation in hydrogen-ion concentration, viscosity passes through a minimum a little on the acid side of *pH*5. Jessen-Hansen found *pH*5 to be the best hydrogen-ion concentration in bread making, and it is also as has been observed, the most favorable for the rising of dough." They also state that their studies indicate that so far as CO_2 production during fermentation is concerned, the best results are obtained near the point of minimum viscosity.

It is also probable that it is due to the favorable action of the hydrogen-ion concentration on the activity of the yeast enzymes that we find that the fermentation period of a dough is materially decreased as we approach that point where the intensity of acidity is most favorable for the optimum baking results.

Cohn and Henderson[9] have summed up quite concisely the value of acidity: "In the first place the desirable length of the fermentation is determined by the acidity of the dough. Increase in the acidity increases the activity of the yeast and shortens the fermentation. Consequently the amount of sugar required by the yeast is diminished (unpublished observations of the authors). Besides, the rate of carbon dioxide production of the yeast within the dough, the tenacity and elasticity of the dough and the escape of gas from the dough are dependent upon the acidity. Experience in this and other laboratories has shown that the best acidity for the baking of bread is indicated by the turning of methyl red from orange to red. In sum, the acidity of the dough at the time of baking seems to be the most important variable factor in bread making."

In this connection the following quotation from an article by Henderson[10] is of interest: "It is possible, however, to measure the hydrogen-ion concentrates of bread by the addition of the ordinary solution of methyl red (0.02 per cent in 60 per cent alcohol) to the pale cut surface of the loaf. Three or four drops of the indicator should be placed upon a single spot and two minutes should be allowed to pass. Then, if the color is a full red without an orange nuance, the hydrog-

[10] *Science*, vol. 48, p. 247 (1918).

on concentration is approximately 10^{-5}N, or more. If n orange tint develops, greater amounts of acid should e added to successive batches of dough until the test vith bread just gives the desired color. . . ."

So far as "rope" is concerned, it has been clearly stablished that the growth of the *bacillus mesentericus* vhich causes rope is practically inhibited at a *pH* of bout 5.

Summary

The chemical phases of the maturing of flour, in particular the action of chlorine, have been described. The nain conclusions to be drawn from the foregoing discussion may be summed up as follows:

Any treatment of flour, to condition it for its best aking results, which does not increase the intensity f its acidity does not condition the flour in the same nanner as such flour is conditioned in storage. As essen-Hansen[11] has so aptly put it: "Of the different rtificial means advocated in recent times as being apable of ameliorating flour, none are of value other nan those which increase the hydrogen-ion concentraion in the dough."

The proper control of the intensity of the acidity of our, such as may be accomplished through treatment vith chlorine, or any other means which accomplishes ne same results, affects favorably those factors which re so essential to the satisfactory baking efficiency of flour.

The optimum intensity of acidity for the best results s such that methyl red should just turn red without ny orange nuance when this indicator is applied to ne freshly cut surface of the oven product. This nange in the color of the indicator is produced when ne concentration of the hydrogen ions is about 10^{-5} ormal, or, in other words, the *pH* is about 5.

The intensity of acidity is that factor which, under roper control, favorably affects the dough viscosity, y reducing it toward its minimum and, at the same me, produces those changes which increase the elasticy of the gluten. It lessens the period of fermentation y increasing the activity of the yeast. It also acts avorably in the control of "rope."

Flour which has been submitted to the chlorine treatent is stabilized in the sense that its improved baking apacity remains constant for many months. This abilizing is brought about by arresting the actions of ose enzymes to which is due the increase in acidity f an untreated flour when stored.

The acidity of flour is its most important variable. ence the treating of flour with chlorine and the conequent production of the optimum intensity of acidity at once a great asset to the miller as it is to those ho use his output and that means each and every one f us. This means of controlling this important factor -acidity—is a great advance in the milling art. Now, ne flour buyer can obtain a stabilized flour at its nhanced baking capacity. Although not previously scussed, it may not be amiss to say that such chlorineeated flour is stabilized in yet another sense, and this of importance too. Such flour is much less readily ubject to the usual rancidity, mold and insect festation.

Part II, dealing with the method for treating flour ith chlorine on a commercial scale, will be published a subsequent issue of "Chemical and Metallurgical ngineering."

Some New Sources for Vegetable Oils

The development of tomato catsup and soup manufacture has resulted in a great production of tomato seed each year that has been going to waste. The oil from these seeds has been found after refining to be a suitable food oil. By pressing, the yield is about 18 per cent of the dry weight of seed, and if a solvent is used the yield is increased to 20 or 22 per cent. In Italy, where the tomato-pulping industry has been developed on a large scale, tomato-seed oil is a commercial product. It is estimated by the Department of Agriculture that the equivalent of 1,500 tons of dry seed is produced annually in the United States.

The sunflower is a possible source of oil, a large quantity of it having been made from sunflower-seed in Russia before the war. The cold-pressed oil is used for culinary and other purposes where a high-grade edible oil is required, while the hot-pressed is employed in making soaps and Russian varnishes. In 1911, more than 500 mills in the Caucasus were engaged in pressing sunflower seed. It is possible that the sunflower may some day be an important oil-producing plant in this country. The crop is now grown to quite an extent in some parts of the country, notably Missouri, for poultry feed.

Considerable quantities of okra seed could be produced every year by letting the plants ripen seed after the harvesting season is over. This seed contains about 18 per cent of an oil that much resembles cotton-seed oil; in fact, okra and cotton belong to the same, botanical family.

Cohune nut oil, which is obtained from the fruit of a variety of palm tree that grows in Central and South America, has been examined by the department. It resembles coconut oil and can replace it for many purposes. The supply of these nuts is almost unlimited and several firms are now attempting to establish the manufacture of the oil on a commercial basis.

Swiss Aluminum Industry

Before and during the war the policy of the Swiss aluminum industry was directed towards supplying German industries with aluminum, according to a recent number of *The Iron and Coal Trades Review*. The depreciation of the mark and the increase in German aluminum production during the war however, induced the German industries to abandon the Swiss metal. While, in 1913, 5,645 metric tons of aluminum and in 1920 even 3,542 tons were exported to Germany, the exports dropped in 1921 to 1,646 tons. This compelled the Swiss aluminum industry to look for new markets, which were found in 1921 in the United States and Japan. Thus in 1921, 3,421 tons of aluminum found their way to the United States, and 894 tons to Japan. Besides this, Switzerland's aluminum industry, which is concentrated in the hands of the Neuhausen concern (capital 42,000,000 fr.) has commenced paying more attention to the aluminum-working industries in Switzerland, and to participate financially in them. At the present time there are in Switzerland a number of mills which roll the metal into bars, plates, tubes and wire, and which exported during 1921, 1,193 tons. Half of this amount went to the United States and one-quarter to British India. Several factories of aluminum vessels and other goods exported close upon 5,000,000 fr. ($1,000,000) worth of goods in 1921.

Book Reviews

MECHANICAL TESTING by *R. G. Batson* and *J. H. Hyde*. Vol. 1: Testing of Materials of Construction. London: Chapman & Hall, Ltd. 413 pp. 1922.

The authors, members of the engineering staff of the National Physical Laboratory, have undertaken to write what can be considered a textbook on mechanical testing. Their excellent work fills a definite and longfelt want for such a book, particularly for one covering Anglo-Saxon technique.

In discussing the standard shape of "load-extension curve," p. 30, would it not be advisable to call attention to the fact that these curves from recording machines are always misleading in their appearance, since the "maximum load" is indicated for a cross-sectional area of the specimen which no longer exists when that load is reached. Irregularities in curves, when the metal passes from the elastic to the plastic state, can not be explained by inertia of the elastic system present in the apparatus; these irregularities are present in irons and plain carbon steels, but not at all in other metals. This link in the curve is still an unsolved problem; it seems that no means are as apt to solve this mystery as Dalby's optical load-extension recorder.

While theoretically the use of dead weights is the best method for calibration of testing machines, the "standardizing boxes" mentioned under paragraph 52 have been found to be quite accurate and constant, both in tension and compression, and they certainly are very much handier than dead weights or calibrating levers.

The title of Chapter XVIII, "hardness and abrasion tests," is confusing, since hardness (commonly interpreted as "resistance to permant deformation") and resistance to abrasion are properties of entirely different nature and should be treated separately. The confusion in the field of hardness testing is already so large that nothing should be done to increase it. Furthermore, the reviewer cannot agree with the authors' two categories of methods for testing hardness. Abrasion and scratch tests are of different nature. In the abrasion or "wear" test (which is not a hardness test) particles of the material are progressively torn away. In the scratch test of Turner, Martens or the "microcharacter" a groove is obtained by successive compression of the metal over adjoining micro-sections of the surface; it therefore is also an indention test. The definition of hardness as "resistance to permanent deformation" is in no way disturbed by measuring hardness by a scratch test. It must be kept in mind that no "indentation" test gives any information on the resistance to abrasion.

In this connection, I believe it incorrect to state (as the authors do in paragraph 188) that the abrasion test has been applied as a scratch test or as a drill test; abrasion resistance can be investigated only by abrasion. Drill tests are again of entirely different nature. We must differentiate between the micro-drill test of Jaggar which—like the diamond or sapphire scratch test—is a test for the comparative hardness of the individual crystals, and the drill test of Bauer, Keep, Kessner or Ludwik, who, by means of a large steel drill, investigated the resistance of metals to drilling in order to determine their "machineability." In the section on small machines for determining Brinell hardness of thin sheets (paragraph 182) the special machine developed for this purpose by Brinell and made by the Alpha Co. should be mentioned, as later machines are patterned after Brinell's. One might mention that the Brinell or other indentation hardness of thin sheets, as far as annealed stock is concerned, is of rather doubtful value; the Erichsen cupping test will be found more convenient, and it yields more direct information on how the material will "work." It is perhaps superfluous to remark that depth indicators (paragraph. 185) should never be used while the metal is exposed to pressure, "during the test," but only after the load has been released. The first instrument of this kind, of the mercury capillary type, was designed by Brinell and is still being made by the Alpha Co. All depth indicators give very confusing results and for this reason the measurement of the diameter of Brinell impressions is preferred by most of the American laboratories.

The "Auto Punch" described in great detail on pp. 286 and 287, recently imitated by several German apparatus manufacturers, does not give results comparable to Brinell numbers, as the resistance of metals to impact penetration is quite different from that to static ball pressure and this factor varies with the alloy. Besides this fundamental point which in itself excludes accurate results, the springs in these instruments cannot remain constant in usage. The "Waldo hardness tester," pp. 288 to 289, might be eliminated, as this instrument, for obvious reasons, is not in use anywhere.

Methods and apparatus for investigating the cutting efficiency of tool steels are not mentioned; these investigations are as difficult to carry out as they are important and it is to be hoped that the authors will discuss them in detail in a future edition of their book, particularly since splendid work in this direction has been carried on at Sheffield for a number of years.

These few points where the reviewer is inclined to disagree with the authors, should not be allowed to overshadow the thousands of accurate facts contained in the book.

In general, Batson and Hyde's book is very well written, clear and concise, and it gives much valuable information on the technique of mechanical testing. It should be on the desk of every metallurgist and engineer of materials. It will also serve admirably as a textbook in college courses on mechanical testing; in fact, the testing of the mechanical properties of metals should form and will ultimately form an important part of the curriculum in metallurgical engineering, as well as in mechanical engineering.

HERMAN A. HOLZ.

Steel Worker's Handbook

"HÜTTE," TASCHENBUCH FÜR EISENHÜTTENLEUTE. Published under the auspices of the *Akademischen Verein Hütte*, Berlin. Second Edition. *Prof. Hanemann*, Editor-in-Chief. June, 1922. Wilhelm Ernst and Son, Berlin, Germany. 963 pages, 511 illustrations 738 marks.

Hütte has been the constant companion of more than one generation of Continental engineers, and editions of various dates are to be found in the working libraries of many Americans. Covering in a comprehensive manner the entire field of engineering it could only be supplanted by a collection of handbooks covering civil, mechanical, electrical, metallurgical and mining engineering. In 1910 it was decided to collect together the material applying directly to the engineering of iron and steel works and foundry and supplement it by auxiliary material sufficient for a self contained separate volume. The present book is the second edition of this separate. It has been thoroughly revised by an imposing array of *Prof., Dr.-Ing. Geh. Reg.-Rat., Direktors*, etc., and over 100 new pages added.

It is principally concerned with the design and construction of iron and steel works and foundries. Little attention is paid to metallurgical practice—for instance, the details of a converter and its accessories occupy 18 pages while 3½ suffice for the "metallurgy and operation." No attempt is made to discuss the properties of the resulting product. But in the field of design and construction it is quite comprehensive, outlining an enormous amount of material on all branches of the industry from coke oven, through the power plant, blast furnace, steel making departments, to the rolling mills, not forgetting such specialties as sheet coating departments, hammer and press work, pipe making, wire drawing and the manufacture of wire products. An excessive amount of space—about 50 pages—is given to roll design and rolling mills are discussed at length and in great detail.

Therefore, while the book would undoubtedly be of great use to a engineer engaged in the design and construction of steel works, it is of only secondary interest to the operator or metallurgical engineer and practically of no use to the purchaser of fabricator, foundry, machine shop, or manufacturer of metallic articles. An attempt has been made to widen the scope of the book by including a pre

iminary section on Allied Sciences. This contains an outline of metallographic practice, and an especially good description of the binary alloy systems between iron and all the common elements. Another notable chapter is on the thermal characteristics (and methods for such determinations) of metals, slags and refractories. An outline of qualitative and quantitative analysis of steels and furnace and coke oven materials and products is also included.

From a book-lover's viewpoint, the present volume, when compared with the pre-war editions, is a vivid reminder of the economic plight which has descended upon Germany since their failure to grab world dominion. The old volumes are bound in delightfully rich, smooth and flexible leather, and printed on the finest coated paper. The present edition is on paper suspiciously like news print, and the binding is like that which we are given on the latest "best sellers."

E. E. THUM.

Recent Chemical & Metallurgical Patents

British Patents

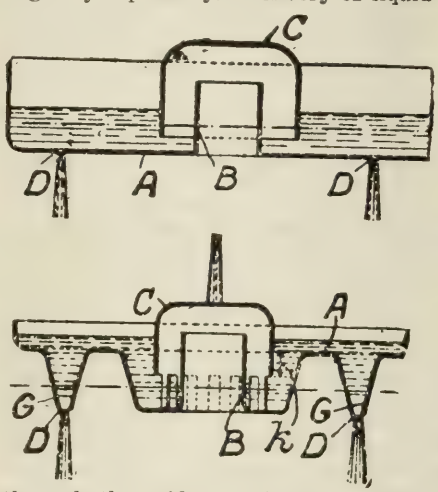
For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Activated Carbon — Active charcoal is made by impregnating lignite or peat or a coked product thereof with caustic alkali or alkali carbonate, heating to a high temperature and removing the alkali. The activity is increased by subjecting the material to a partial vacuum before impregnation. (Br. Pat. 178,779. W. Carpmael, London. June 21, 1922.)

Anthraquinone — Anthraquinone is prepared by condensing orthobenzoylbenzoic acid with sulphuric acid of 75 to 80 per cent strength. The process may be made continuous by continuous addition of molten ortho-benzoylbenzoic acid and by maintaining the strength of the sulphuric acid either by evaporation such as by blowing in air or by addition of oleum. The anthraquinone separates on cooling from the comparatively weak acid. (Br. Pat. 176,-335. F. W. Atack, Manchester. April 6, 1922.)

Oleomargarine Manufacture—In the manufacture of margarine and other edible fats especially from vegetable fats, an oleaginous material having "water-dispersing properties" is added to the usual ingredients, or to margarine after manufacture, so that an emulsion is formed having the aqueous liquid as the internal phase in a state of very fine subdivision. The water-dispersing medium may be prepared by heating soya-bean oil and passing air through it until coagulination sets in; oils, such as cotton-seed, ground-nut, or sesame oil, are then stirred in. The watery constituents of the emulsion may consist of water or milk and sugar, glucose, or other fermentable substances, which may contain vitamines and salts may be added. The fermentation of such substances is checked by the film of the water-dispersing medium surrounding the aqueous globules. The emulsion may be dissolved in a suitable fat or oil before adding to the margarine, etc. The water-dispersing medium may be added direct to the coconut oil or other fat from which the margarine etc., is to be made, or part of the medium may be so added and part added in the form of an emulsion. (Br. Pat. 178,885. E. V. Schou, Palsgaard, Denmark. June 21, 1922.)

Dephlegmating Column—A bubbling device for a rectifying or other column comprises a plate *A* having capped chimneys *B* for the passage of gases and one or more orifices *D* in the plate through which liquid descends to the next lower plate, the cross-section of the orifices being such that the liquid filling them adheres to their edges by capillarity. Delivery of liquid



through the orifices and the height of liquid on the plates vary according to the supply of ascending gas. A circular guide-wall may surround the cap *C*, and, in a further modification, the quantity of liquid required on a plate may be reduced by the formation of funnels *G* terminated at their lower ends by the orifices, the minimum height of the funnels being the distance *k* between the solid edge of the caps and the bottom *A* of the plate. (Br. Pat. 178,852. Not yet accepted. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude, Paris. June 21, 1922.)

Adhesives; Starch—An adhesive is made by treating potato starch paste with an alkaline or a neutral peroxide in presence of an alkali in a quantity insufficient for the production of soluble starch. Suitable per-salts such as persulphates, percarbonates and perborates or the peroxides of barium, calcium, magnesium, zinc or hydrogen may be used. Alkali carbonates or alkaline earth hydroxides may be added when neutral per-salts or peroxides are used. In an example, 100 kilos potato flour are mixed with 2½ kilos ammonium persulphate and 1 kilo ammonia solution of 22 deg. Bé. (Br. Pat. 179,765. A. G. Bloxam, 30 Southampton Bldgs., Holborn, London. July 5, 1922.)

Extracting Essential Oils — Essential oils and like volatile products are extracted from solid materials such as sandal wood, by means of a heated gaseous vehicle such as nitrogen or other inert gas or an unsaturated

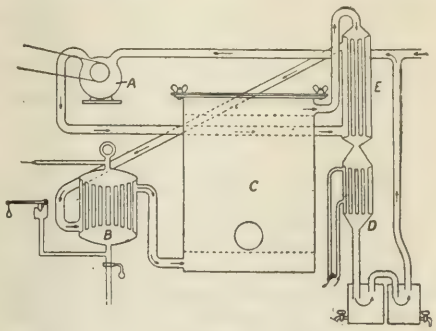


FIG. 1

vapor which is not condensed on cooling to separate the essential oil or by means of steam which is condensed in such a way as to generate a further quantity of steam for use in the extraction. In using an inert gas, the gas is circulated in a closed circuit through a heater *B*, Fig. 1, extraction-vessel *C*, heat-exchanger *E*, condenser *D*, pump *A*, and back through the heat-exchanger *E* and heater *B* to the vessel *C*. The heater may be formed as a jacket surrounding the vessel *C*, and containing a steam coil on an electric heater. Steam, when used, is passed through an extraction vessel *S*, Fig. 2, and to a condenser *E* which forms a vacuum evaporator, for example of the Kestner climbing-film type. The condensation of the steam and essential oil serve to generate steam at a lower pressure, which is compressed by a pump *C* and passed

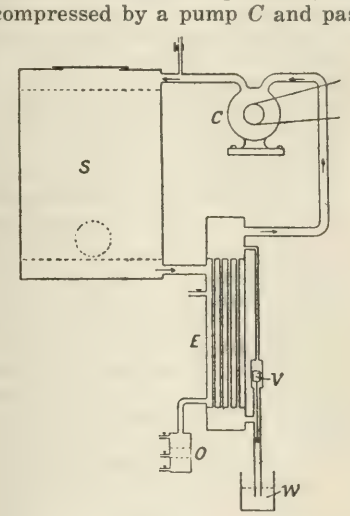

FIG. 2

into the extractor-vessel. The condensed water is separated from the essential oil in a vessel *O* and may be passed into the well *w* to be evaporated in the condenser. A float device *v* serves to maintain a definite level of water in the condenser. (Br. Pat. 176,104. F. L. Usher. Bangalore, India and E. P. Metcalfe, Hove, Sussex. April 26, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Shortridge Speech Came Too Late

Might Have Saved the Dye Embargo Had Results of Monopoly Probe Been Officially Announced in Advance of Senate Vote—Chances Now Are Against It

HAD SENATOR SHORTRIDGE of California acquainted the Senate with the fact that his investigation of the dye industry had disclosed no irregularity in the conduct of the domestic dye industry and with the fact that his painstaking probe had disclosed nothing approaching a monopoly in this industry, before the vote on the embargo was taken rather than afterward, it is believed several votes which were cast against the embargo would have been registered for it.

The Senate investigation of the conduct of the dye industry was completed several weeks ago. No formal report as to the conclusions of the sub-committee, which conducted the investigation, has been submitted. There also has been a long delay in making available printed copies of the testimony taken at these hearings. While it had been assumed very generally that Senator Shortridge would report that no proof of monopoly or other wrong-doing had been disclosed, his statement made after the roll-call on the dye embargo was the first authoritative announcement of that conclusion. For that reason friends of the embargo are hopeful that the complete vindication of the domestic industry, which was announced in such a belated manner, will influence some of the Senators who voted against the embargo in Committee of the Whole to vote for it in the Senate proper in view of this finding.

Vote Likely to Stand

On the other hand it is recognized that it is very difficult to induce Senators to change their position after a record vote has been taken. It is admitted very generally in well-informed legislative circles that the chances are against a favorable vote for the embargo when a vote is had on Senator Frelinghuysen's amendment, which proposes to re-insert the embargo provision in the bill. If the President should use his influence actively in behalf of the embargo it is admitted that the chances then would favor its adoption by the Senate.

How the Senators Voted

Senators voting for the embargo when the Committee of the Whole rejected the Finance Committee's amendment were: Ball, Delaware; Brandegee, Connecticut; Bursum, New Mexico; Calder, New York; Curtis, Kansas; du Pont, Delaware; Edge, New Jersey; Ernst, Kentucky; Fernald, Maine; France, Maryland; Frelinghuysen, New Jersey; Gooding, Idaho; Hale, Maine; Jones, Washington; Ladd, North Dakota; Lenroot, Wisconsin; Lodge, Massachusetts; McCumber, North Dakota; McKinley, Illinois; McLean, Connecticut; McNary, Oregon; New, Indiana; Oddie, Nevada; Pepper, Pennsylvania; Phipps, Colorado; Rawson, Iowa; Shortridge, California; Sterling, South Dakota; Townsend, Michigan; Warren, Wyoming; Watson, Indiana, and Willis, Ohio.

Senators voting against the embargo were: Ashurst, Arizona; Borah, Idaho; Capper, Kansas; Caraway, Arkansas; Culberson, Texas; Cummins, Iowa; Dial, South Carolina; Fletcher, Florida; Harreld, Oklahoma; Harris, Georgia; Harrison, Mississippi; Heflin, Alabama; Johnson, California; Kellogg, Minnesota; Kendrick, Wyoming; Keyes, New Hampshire; King, Utah; McCormick, Illinois; Moses, New Hampshire; Nelson, Minnesota; Nicholson, Colorado; Norbeck, South Dakota; Norris, Nebraska; Overman, North Carolina; Pomerene, Ohio; Ransdell, Louisiana; Robinson, Arkansas; Sheppard, Texas; Shields, Tennessee; Simmons, North Carolina; Smith, South Carolina; Smoot, Utah; Stanley, Kentucky; Swanson, Virginia; Trammell, Florida; Underwood, Alabama; Walsh, Massachusetts; Walsh, Montana.

Twenty-six Senators did not vote, Most of them were paired, but two additional votes at least would have been cast for the embargo had they been present.

Carnegie Tech to Teach Metallurgy to Naval Officers

Carnegie Institute of Technology at Pittsburgh has been selected by the United States Naval Academy at Annapolis to give advanced courses in metallurgy to its graduate officers. Beginning next September, the Naval Academy will send two ordnance officers, graduates of the Academy, for a year's study in advanced metallurgy. Their studies will be confined principally to advanced metallurgy but will include some studies in electricity and physical chemistry. Other groups of graduate officers are assigned each year to various colleges or universities to study along specialized lines.

F. F. McIntosh, associate professor in metallurgy at Carnegie Tech, will supervise the studies of the naval officers. Lieutenants Gilbert C. Hoover and John H. Keefe have been assigned to take the work the next college year.

Says Dye Embargo Is Working Well

Dickson Describes Work of Treasury Department in Controlling Imports

In recent testimony before the House Appropriations Committee, F. S. Dickson, in charge of the dye and chemical section of the Treasury Department referred to the work of the section in controlling dye imports.

The section bases reasonable prices on dyes upon the relation between the American cost of production and the American selling price, unless it can be shown that the cost of production abroad is comparable. It does not base a reasonable price upon the relation between the American and foreign prices. Mr. Dickson stated that for some articles of which there are small sales, moderately large profits are obtained.

Mr. Dickson said he had not found any profits in the dye manufacturing business in this country. About 10 per cent of the American consumption of dyes is imported. Because of the temporary tenure of the dye section it has been unable to determine whether the American industry is able to supply the domestic dye needs to the advantage of the manufacturer and consumer. He referred to the fact that the section is handicapped in having a laboratory.

Keeping Out Foreign Dyes

It was further testified by Mr. Dickson that the dye embargo so far has kept out foreign dyes. This year a total of 6,200 permits for importation of dyes have been issued for materials the domestic manufacturers could not supply. He had not observed a case of excessive charges, although suspicion had attached to one case and the price came down. He referred to the possibility of dyes being imported unlawfully through false billing which could be detected only by chemical analysis. Some imports have been checked at New York but have been found satisfactory. Ninety per cent of the imports are through New York, with a few through Boston and Philadelphia. The imports are largely from Germany and Switzerland, with a few from France and England.

Chemical and Engineering Societies Pledge Support to the Chemical Foundation

Federation's Committee on Procedure Asks Harding to Save Chemical Patents—Representatives of American Chemical Society Refused a Hearing at the White House

APPARENTLY the Department of Justice has lost some of the enthusiasm which characterized its initial activities against the Chemical Foundation. The administration is hearing from the country and at the White House inquirers are told that the Chemical Foundation case is a Department of Justice matter. Such an avalanche of protest has reached Washington that there is an entirely different attitude in evidence at the Department of Justice and at the office of the Alien Property Custodian, nevertheless there is no lessening of the determination to go ahead with the suits.

The announcements and statements made by officials of the Department of Justice and by the Alien Property Custodian's office indicate that the case against the Chemical Foundation is a legalistic structure in which more importance is attached to technicalities than to the fate of a great American industry. Apparently, the prosecuting officers launched into the case without full understanding of it, as is indicated by the inaccuracies in their written and verbal statements.

Federated Engineers Appeal to President to Save Patents

That the Chemical Foundation enjoys the confidence of substantial interests outside of the chemical industry is indicated by the action of the Federated American Engineering Societies in adopting the following resolution:

> Whereas the President of the United States has ordered the Alien Property Custodian to recover that part of the patents formerly owned by enemies sold to the Chemical Foundation and
>
> Whereas these patents have become the nucleus of our American synthetic organic chemical industry which must be encouraged for scientific research, public welfare and national defense
>
> Therefore be it resolved that the Federated American Engineering Societies, through its committee on procedure, expresses the hope that no action will be taken without hearing representatives of chemists, chemical manufacturers, the medical profession and others most directly concerned and implores that nothing be done which can in any way or to the slightest extent tend toward the ultimate return to former owners of patents or other property lawfully sequestered and sold to Americans.

In announcing this resolution, Dean Mortimer E. Cooley of the University of Michigan and president of the Federated Engineering Societies emphasized the fact "that the Federated American Engineering Societies speaks concerning national problems for thirty-odd national, state and local engineering societies. The federation, therefore, speaks on behalf of some 55,000 engineers."

The Federation's Committee on Procedure includes Dean Dexter S. Kimball of Cornell, J. Parke Channing of New York, William McClellan of Philadelphia, and William E. Rolfe of St. Louis. Its chairman is Calvert Townley, vice-president of the Westinghouse company.

Told That "Chemists Had Too Many Committees"

So that the President might have the advantage of the views of a group of prominent men interested in the promotion of chemistry as a science, the American Chemical Society on July 12 sought an interview with the President for a committee which had been named. The request was followed up by telephone without result, and later a member of the committee called at the White House to inquire about it. He was told by the President's secretary that the chemists had too many committees. He apparently is of the opinion that since an interview had been granted to the committee headed by Dr. Herty, this should be sufficient. The secretary's attention was called to the fact that the interest of the American Chemical Society is different from that of the manufacturing chemists.

This attitude was confirmed on the following day by the receipt of a perfunctory statement from the President's secretary to the effect that the President is too busy with the coal strike to arrange to receive the committee from the American Chemical Society. In view of the fact that he is receiving a great many other persons, the reply is not entirely satisfactory.

Intentions of Committee

Had the American Chemical Society committee been granted an interview it was the intention of its members to tell the President that, so far as they have been able to learn, the purposes of the Chemical Foundation are laudable and that it has been conducted without irregularities. A representative of the chemists' committee had listened to a two-hour explanation of the position of the Department of Justice without having elicited any information as to illegal conduct on the part of the Foundation. In view of those facts, President Harding was to be asked if he had any information which he could impart to them, in confidence if necessary, which would indicate that the society is wrong in placing its support behind the Chemical Foundation. The members of the committee had hoped to tell the President that, in the light of all the information they have been able to gather, they can see no reason for this blow dealt to research.

Personnel of Committee

The Chemical Society's committee is composed as follows: Edgar F. Smith, president American Chemical Society and former provost of the University of Pennsylvania; John E. Teeple, consulting chemist of New York City and treasurer of the American Chemical Society; Julius Stieglitz, of the University of Chicago and former president of the American Chemical Society; William Hoskins, consulting chemist of Chicago; E. R. Weidlein, director of the Mellon Institute of Industrial Research; Arthur D. Little, past president of the American Chemical Society and of the American Institute of Chemical Engineers, and a member of the corporation of the Massachusetts Institute of Technology; J. F. Norris, professor of organic chemistry at the Massachusetts Institute of Technology; R. H. McKee, professor of chemical engineering at Columbia University and past chairman of the New York section of the American Chemical Society; George D. Rosengarten, member of the national policy committee of the American Chemical Society, and H. E. Howe, editor of the *Journal of Industrial and Engineering Chemistry*.

Atmospheric Pollution Litigation Held in Abeyance

Although one of the cases was decided many years ago and the other was filed six years ago but not prosecuted, the U. S. Supreme Court continues to maintain on its docket two chemical cases of general interest. One of these is the State of Georgia vs. the Tennessee Copper Co., involving smelter fumes. This case was decided by the court more than a dozen years ago and the company was required to prevent the destruction of vegetation through further exhaust of fumes. The court retains the case on its docket from year to year, however, on the ground that it does not care to lose jurisdiction in the matter should any new developments arise in the situation.

The other case is that of the State of New York vs. the Bulls Ferry Chemical Co. of New Jersey, which was filed by the state in the court on March 11, 1916, but which has never been prosecuted. In this case the State of New York sought to restrain the operation of a factory of the chemical company at Edgewater, Bergen County, N. J., on the ground that the fumes, smoke, gases and other vapors emitted by the plant are offensive, obnoxious and destructive to New York, principally the residential district on Riverside Drive.

The constitutionality of the federal water power act in its application to state streams, brought by the State of New York just before the last term of court adjourned, will be carried over on the docket for the new term beginning in October.

New York University Offers Courses in Raw Materials

New York University announces two new evening courses in the geology of commerce and finance beginning this fall. The purpose of the courses is to acquaint the student with the fundamental facts underlying our mineral and raw materials situation. The character and source of supply, the methods and cost of preparing them for market and their relation to other lines of business will be discussed in a series of lectures. The subjects will include building stone, lime and cement, brick and tile, water supply, sulphur and pyrites, salt, borax, fertilizer fuel and power.

Ernest R. Lilley, the lecturer, is an experienced geologist and mining engineer and one of the best informed men in the country on the economic problems of the raw material industries.

The second term, beginning in the spring, will cover the more complex problems of the metal industries. The lecturer will divide his subject into four main divisions—the iron group, the non-ferrous metal group, the precious metals, and the process minerals. Because of the special problems involved in preparing these materials for the market, stress will be laid upon the nature and cost of smelting and refining.

Alpha Chi Sigma to Reorganize Alumni

At the seventh biennial conclave of Alpha Chi Sigma, the professional chemical fraternity, held recently in St. Louis, a plan was adopted for the organization of the alumni into professional groups. This reorganization had been looked forward to since the previous conclave of 1919, at which time the old scheme of alumni organization was discarded and the various alumni groups were asked to form, test out, and report at the next conclave their various plans for reorganization.

The plan accepted is a compromise on the various plans submitted and it is believed the first step has been taken toward the organization of professional groups to replace the previous alumni chapters.

The following officers were elected for the next two years: President, Dr. Stroud Jordan, Brooklyn, N. Y.; vice-president, Dr. Robert Burns, New York City; secretary-treasurer, A. L. Davis, Wood River, Ill.; National Alumnus, L. J. Trostel, Bureau of Chemistry, Washington, D. C.; editor of *Hexagon*, John R. Kuebler, Indianapolis, Ind.

Chemical Warfare and Muscle Shoals Appropriations

Construction work, at a cost of $262,000, for the Edgewood Arsenal of the Chemical Warfare Service and also for Camp Lewis, Washington, is authorized by the War Department appropriation bill passed by Congress and approved by the President.

The Chemical Warfare Service also receives $17,240 for administrative expenses and $600,000 for investigations.

For construction of Dam No. 2 at Muscle Shoals, Ala., $7,500,000 is appropriated, but it will not be available until October 1.

Preliminary Program for A. I. M. E. Meeting

Society Will Journey to Coast by Special Train, Picking Up Members En Route

A preliminary program of the 126th meeting of the American Institute of Mining and Metallurgical Engineers has been announced. The meeting is to be held in San Francisco, Sept. 25 to 29.

A party including President and Mrs. Dwight will be made up in the East. It will pass through the central western and northwestern states, and, it is hoped, will be joined by members from those states. The party will arrive in San Francisco on Sept. 24.

Monday, Sept. 25, will be devoted to technical sessions which will be held at the Engineers Club and there will be as many sessions as may be required to present the papers available. Owing to the lateness of announcing the meeting in San Francisco, several papers that should be presented at this meeting will not be prepared in printed form for distribution prior to the meeting.

The following day, a party limited to 50 men will leave for Hetch Hetchy, San Francisco Water Project, under direction of M. M. O'Shaughnessy, Chief Engineer. Those not taking this trip will visit a number of interesting points in the vicinity of San Francisco. These trips will occupy four days up to Sept. 30, when the party will take the train for Los Angeles. The program provides for a one-day stop in this city and in Kingman, where the mines and mills in the vicinity will be visited. The return trip allows for stops at the Grand Canyon, the Roosevelt Dam and the Apache Trail.

Among the papers to be presented are the following:

"Deposition of Copper Carbonate from Mine Water," by P. D. Wilson.

"Surface Tension and Adsorption Phenomena in Flotation," by A. F. Taggart and A. M. Gaudin.

"Conditions of Stable Equilibrium in Iron-Carbon Alloys," by H. A. Schwartz, H. R. Payne, A. F. Gorton and M. M. Austin.

"Neumann Bands as Evidence of Action of Explosives on Metal," by F. B. Foley and S. P. Howell.

"Effect of Nickel Chromium on Cast Iron," by Richard Moldenke.

"Shot Firing by Electricity," by N. S. Greensfelder.

"Automatic Electric Regulation of Ball-mill Feed," by B. H. Smith.

"Heating and Cooling Curves of Large Ingots," by F. E. Bash.

"Electrochemical Process for Treatment of Copper and Other Ores," by Henry S. Mackay.

"Industrial Relations in California Petroleum Industry," by Roy W. Kelley.

"From Drill to Service Station—The Story of Oil in California," by Roy W. Kelley.

"Mining Iron Ore in the Adirondacks," by John E. Hodge.

Societies Will Meet at Chemical Exposition

The next regular meeting of the recently organized Technical Photographic and Microscopical Society will be held in conjunction with the Eighth National Exposition of Chemical Industries during the week of September 11 to 16 at the Grand Central Palace New York, on Thursday, September 14. In addition to meeting, the organization has already made arrangements for the display and explanation of the work of individual members in technical photography and photomicrography with its application to the everyday problems of the chemical or chemical consuming plant. A booth at the exposition has been reserved for the purpose.

Other associations, announcement of whose meetings in conjunction with the Chemical Exposition has already been made, include the Salesmen's Association of the American Chemical Industry, the American Ceramic Society and the Technical Association of the Pulp and Paper Industry. Later announcements of the programs of these societies will be made.

Powdered Coal for St. Louis Power Plant

Recommended as a Means of Guarding Against the Emergencies of Future Coal Strikes

Decision to burn powdered coal in the new $6,000,000 power plant of the Union Electric Light & Power Co. of St. Louis has been announced by the company's engineers, McClellan & Junkersfeld, Inc.

Extensive tests and investigation of stoker equipment and pulverized fuel equipment proved that coal in powdered form was a most desirable fuel giving more economical results than any other type of combustion equipment and permitting the use of mine sweepings, low grade and non-marketable coals, which are often wasted.

The possibility of using such waste coals is of very great advantage, from the standpoint of economy. The burning of powdered coal is as simple as the burning of fuel oil, has many of the advantages of this fuel, and, in case of emergency due to miners' strikes or other unforeseen causes, fuel oil may be used in the same furnaces without change.

The new plant, of which 60,000 kw. will probably be in operation next year, will have an ultimate capacity of 240,000 kw., and is to supply the rapidly increasing industrial and lighting load in St. Louis, in addition to that now being supplied from the Keokuk dam and from an existing large steam plant

troleum Committee Conference mends Gasoline Specifications

The Interdepartmental Petroleum ndards Committee of the Governnt held an open conference in Washton, July 3. At that time the comtee was again urged to amend the vernment specifications for gasoline increasing the "end-point" of the tillation test. It was urged by some ers in attendance that the demulsiity test also be modified, or for ne products eliminated from the cifications. Numerous other changes detail were also proposed. The mmittee will take these matters unadvisement at an executive meetto be held in the very near future er which the results of their delibtions will be announced. As in the t, the specifications recommended by s committee will undoubtedly be the cial basis for government purchases. r that purpose they require approval the Federal Specifications Board this approval will doubtless be nted promptly, as the committee resents all of the interested departnts.

New Chemical Companies

Fewer companies for the manufacre and distribution of chemicals, dyes l drugs were organized during June n in any month since May, 1921, ording to the compilations of the w York *Journal of Commerce*. The toindicated investment of the nine new mpanies was $2,600,000, which comes with an aggregate of $3,671,000 the twenty companies organized ring May, 1922. The record for the sent year was made during January en an investment of $37,650,000 was licated.

The names and indicated investment the nine companies formed during month of June are as follows:

rier Chemical Co.	$150,000
hardt Medicine Co.	50,000
chris Corporation, The	750,000
ific Ammonia & Chemical Co.	300,000
ack(Dr.) Health Products Corporation	100,000
nsylvania Pharmacal Co.	100,000
wartz Drug Co.	100,000
ndard Flexible Compound Co.	1,000,000
(W. J.) & Sons Co., Inc.	50,000
otal	$2,600,000

r Reduction Co. to Manufacture in Birmingham

Announcement is made that the dquarters, office and plant of the Reduction Sales Co. will be reved from Atlanta, Ga., to Birmingn, and that a $250,000 plant will be cted in North Birmingham, where es and equipment for the oxyacetyle welding and cutting will be manutured.

The site for five of the buildings has eady been purchased and consists of ee and one-half acres at Twentyth Ave. and Twenty-fifth St., North mingham. The products of the con will consist of oxygen, acetylene, rogen, argon and other atmospheric ducts, welding and cutting apparatus and supplies, acetylene generators, and specially designed machines for welding and cutting.

L. B. Allen, field representative, will arrive in Birmingham within a few days to begin construction of temporary buildings.. The permanent plant is expected to be completed by January 1, although it is stated that the concern will be in operation in two or three months, as soon as the temporary buildings are ready. The plant will be in charge of H. G. Boyer, district sales manager.

Arsenic Tariff Causes Senate Flurry

Southern Senator Accuses Smelting Interests of Attempting to Profit Unduly at Expense of Boll-Weevil Sufferers

Although a duty of two cents per pound on white arsenic had been approved by the Senate over two weeks ago, the subject was reopened on July 21 when Senator Smith of South Carolina made the startling charges that this tax on insecticide users was made in order to increase the profits of the smelting interests, principally those of the Guggenheims.

"To date," said Senator Smith, "the Department of Agriculture has spent something like $12,000,000 to find some method of checking the boll weevil, the ravages of which insect to a great extent remain unchecked. Now we have some hope in the application of calcium arsenate and the Senate votes a tax that will add 50 cents per acre for every acre poisoned. There are 35,000,000 acres of cotton land in the South and if it were possible to poison all of these fields, this would mean an added cost of something like $17,000,000."

The Insecticide and Disinfectant Manufacturers Association of New York City brought the arsenic duty to the attention of Messrs. Underwood, Smith, Simmons and other Southern Senators. The association estimated that 16,000 tons of arsenic would be needed this year to supply the demand of cotton planters and orchard owners, and that the shortage would be 3,000 tons. The greatest annual production in this country on record is 11,500 tons. Japan is the principal source of the imported arsenic.

Smoot Defends Duty

Senator Smoot challenged the statements of the Carolina Senator, declaring that the greatest amount of arsenic, including that imported, ever disposed of in this country in one year was 20,000,000 pounds, and, therefore, in order to add a burden of between $17,000,000 and $18,000,000 to the poisoning cost, it would be necessary, he said, to use up 90,000,000 pounds of arsenic. The difficulting in reconciling these figures is due, of course, to the fact that Senator Smith's very enthusiastic estimates were based on calcium arsenate tonnage, while Senator Smoot had in mind white arsenic, As_2O_3.

Farmers Using Excess Picric Acid Stocks

That the farmers of the country have not been slow to avail themselves of the opportunity to obtain a good agricultural explosive at a low cost is shown by the fact that in the fiscal year ending June 30, 1922, 3,264,700 lb. of picric acid has been distributed by the Bureau of Public Roads, U. S. Department of Agriculture. Originally about 12,000,000 lb. of picric acid was available as a surplus of war stocks. A considerable amount has been used for road building purposes and there now remains about 5,500,000 lb., practically all of which is located at Wingate, New Mexico. A study of the distribution figures during the past year shows that Minnesota, Wisconsin and Michigan took by far the largest amounts, Minnesota alone taking 1,091,300 lb.

High freight rates and long shipping distances have operated adversely. The unfavorable financial situation in the South also is reflected in the distribution figures. Some twenty states have agree to carry on the distribution during the present fiscal year. The picric acid is being distributed in most cases through the Extension Services. The cost to the farmers is 7 cents per lb. for cartridging and loading plus the freight charges.

Engineering Societies Ask Opinion on Depreciation Regulation

In a letter to the Secretary of War, L. W. Wallace, the executive secretary of the Federated American Engineering Societies, asks what has happened to the appeal of the electrical industries against the depreciation regulation drafted for use in connection with the waterpower act.. Mr. Wallace's letter reads as follows:

"For many months, there has been pending before your Commission an appeal from the electrical industries against the depreciation regulation which it was proposed to enforce in the administration of the waterpower act.

"Many of the engineers who compose this organization are particularly anxious to see our waterpower resources utilized as extensively and as promptly as is possible, and some of them have requested that I secure an authoritative statement as to the status of the matter. There is a feeling that the uncertainty in regard to depreciation is tending to retard this development.

"May I inquire what are the prospects for action on the depreciation regulation? It would be very helpful to our members if we could have the advantage of any personal views on the subject which you may care to express."

Fertilizer Contracts Are Declared Binding

Drop in Price of Nitrate of Soda Involves Losses to Both Farmers and Fertilizer Companies

Contracts made by Georgia farmers with fertilizer companies in 1920 for subsequent deliveries of nitrate of soda are binding, according to the State Court of Appeals. A test case was being brought through the courts and will now be appealed to the Supreme Court of Georgia.

The controversy between farmers and fertilizer companies developed early in 1921. The farmers had placed orders the previous year for nitrate of soda to be delivered in January, February and March, 1921, at $84 per ton. At the time of delivery the market price had dropped to $50, and farmers throughout the Southern States refused to pay the difference. Consequently many suits to recover the difference claimed by the fertilizer dealers were filed. The farmers claim that their loss amounts to $3,000,000. In reply to this, Russell Porter, of Atlanta, president of the Southern Fertilizer Association, issued the following statement:

"The fact is, the contract involved in this suit is the one under which the fertilizer manufacturers of Georgia lost millions of dollars by reason of carrying out their obligations.

"This is only one of the many contracts for fertilizer materials on which the fertilizer manufacturers lost so much money."

Would Repudiate Government Interest in Reparation Dyes

Senator King, of Utah, has introduced a resolution expressing the sense of the Senate that the State Department should annul and cancel any authority on the part of any representative of the United States or other persons to deal with the Reparation Commission "respecting the purchase and importation of reparation dyes into the United States."

The resolution also suggests that the State Department advise the Reparation Commission that the United States Government has no concern with the purchase of reparation dyes for importation into the United States, and that "neither the Textile Alliance, Inc., nor Roland W. Boyden has any authority to negotiate with the Commission on behalf of the government of the United States concerning the purchase and importation of reparation dyes for sale in the United States."

The resolution is prefaced by nine "whereases," in which it is charged that the Textile Alliance has carried on propaganda to mislead Congress into the belief that the government has valuable interests and rights in and to the dyestuffs received from the Reparation Commission from Germany. The King resolution declares that the United States Government has no interest in the reparation dyestuffs, no rights with respect to the proceeds of the sale of such dyestuffs and no interest in the purchase of such dyes for sale in the American market. The resolution charges that the Textile Alliance has made profits of $2,000,000 in traffic in reparation dyes and repudiates the claims of the Alliance for exclusive agency for the purchase and importation of these dyes.

Plans Dye Tariff Amendments

Senator King has announced that he will offer a thousand amendments to the chemical schedule when that section of the revised tariff bill is taken up for final action. He indicated however, that he will debate only a part of these amendments.

Potash Bounty Proposal May Be Extended

The decision of the Senate Finance Committee to put a bounty on potash to replace the proposed duty has caused much discussion of the advisability of extending the plan to other commodities. Some are of the opinion that it could be applied successfully to manganese and other commodities where there is no early opportunity of developing domestically more than a fraction of the country's requirements.

While the sugar bounty, put into effect by Congress in 1890, was unpopular, it was not discontinued for that reason but because sugar is an ideal source of customs revenue, since the tax is distributed to every resident of the country.

In the case of potash, a duty means that the tax will be paid largely by the farmers. A bounty will cost less and will allow that lesser burden to be divided equally among all taxpayers. In the case of manganese, the situation is somewhat different. The tax at the Custom House would fall largely on the steelmakers. In their industry, however, it is comparatively easy to pass the tax on. This means it will be collected ultimately from the construction industries. The tariff makers are particularly anxious to encourage these industries and are trying to avoid adding to their burdens any more than is necessary. This is one of the reasons for the very determined opposition to high rates on ferroalloys. A bounty would distribute the tax better, it is admitted, but the Finance Committee hesitates at launching too heavily into a bounty policy.

Opposition to Potash Duty

Representative Goldsborough, of Maryland, opposing the proposed duty on potash, declared it to be "worse in principle than the ship subsidy. It proposes to subsidize the producers of potash and to make the American farmer pay the tribute to the tune of about $51,350,000 a year."

Mr. Goldsborough gave an extended statement of the American Farm Bureau Federation in opposition to the potash duty.

Civil Service Opening

Competitive examinations are announced by the U. S. Civil Service Commission for Junior Chemist at a salary of $1,200 to $1,800 per year.

Application for this position should be made on form 1312.

Personal

F. L. Childs will continue as sales manager of the Heyden Chemical Co. New York City, following the recent reorganization of the company.

S. F. Cox, formerly assistant to the consulting engineer of the Pittsburgh Plate Glass Co., has accepted a position with the Calorizing Co. of Pittsburgh, Pa., as chief engineer. He will have direct charge of the Wilkinsburg Pa., plant, in addition to other duties.

Philip DeWolf, who has been doing consulting chemical engineering at Westport, Conn., has become associated with the industrial real estate concern, Louis Schlesinger, Inc., of New York City and Newark, N. J. Mr. DeWolf will specialize in industrial and factory real estate.

Thomas French, formerly of Welland, Ontario, Canada, has undertaken the construction of a plant at Albany N. Y., for some metallurgical products. His address at the present times is 363 Edgecombe Ave., New York City.

General Amos A. Fries, head of the Chemical Warfare Service, recently underwent an operation for appendicitis. He is recovering rapidly and expects to be at his desk again before the end of the month.

Dr. George F. Richmond of Antoine Chiris Co., Delawanna, N. J., has been appointed chairman of the nominating committee of the New York Section of the American Chemical Society. Other members are Dr. J. E. Zanetti and S. D. Kirkpatrick.

Julian F. Smith, formerly a member of the research staff of the National Aniline and Chemical Co., Buffalo N. Y., has accepted a position with the Commercial Solvents Corp., Terre Haute, Ind., to become effective Sept. Mr. Smith will have charge of the research and information service.

Ernest T. Trigg, an official of John Lucas & Co., Inc., Philadelphia, Pa., manufacturer of paints and varnishes and president of the National Paint Oil and Varnish Association, gave an address before the first Pacific Coast regional convention of the latter organization, Portland, Oregon, on July 1.

George S. Weith has obtained an indefinite leave of absence from the Redmanol Chemical Products Co. to recuperate from sickness.

Dr. Gerald L. Wendt resigned on July 1 as associate professor of chemistry at the University of Chicago to join the staff of the Standard Oil Company of Indiana in the direction of research.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Car Loading as an Index of Distribution

Production and Consumption of Commodities Are Normally Reflected in the Week-to-Week Changes in the Loadings of Revenue Freight

IN NORMAL TIMES the trend of business movements may be conveniently and accurately followed by observing the changes in the number of freight cars loaded during a certain period. Especially when this figure is studied in connection with statistics of production, is it possible to interpret it in terms of distribution and stocks. In other words when the volume of manufacture exceeds car loadings, stocks are usually piling up. On the other hand an excess of loadings means that distribution is going ahead of production, generally at the expense of lower commodity stocks.

Car loadings also have a qualitative significance in showing the kind of commodities that are entering into consumption. Thus it will be recalled that just before the coal strike started on April 1 there was unusual activity at the mines. March showed abnormally higher coal loadings which favorably affected the total for revenue freight. In April shipments of coal dropped off tremendously and there was a noticeable decline in car loadings during that month. Since that time and in spite of the coal strike there was an increase during both May and June—a very encouraging development as affecting the general commodity situation.

On July 21 the American Railway Association issued its report for the week ended July 8, which was the first since the beginning of the shopmen's strike. The total showed a reduction of 158,577 cars as compared with the last week of June, but 77,784 more than for the corresponding week in 1921. It was less than that in the first week of July, 1920, by almost exactly the same number. It should be pointed out, of course, that some reduction might ordinarily be expected because of the intervention of the holiday on July 4.

Coal loadings showed a decrease of 68,996 cars, a decrease from the preceding week of 25,752 and a decrease of 54,974 as compared with the same week of last year.

Merchandise and miscellaneous freight, which also includes manufactured products, totaled 482,079 cars, a decrease of 93,067 cars as compared with the previous week and an increase of 89,286 cars over the same week of 1921.

Loadings of revenue freight since the first of the year are compared with the corresponding periods of 1919, 1920 and 1921 in Table I.

TABLE I. CAR LOADINGS OF REVENUE FREIGHT, BY WEEKS SINCE JANUARY 1, 1922

WEEKLY CAR LOADINGS OF REVENUE FREIGHT BASED ON REPORTS FROM THE RAILROADS OF THE U. S. BY THE CAR SERVICE DIVISION OF THE AMERICAN RAILWAYS ASSOCIATION

The Arsenic Situation

During the last few weeks there has been an acute shortage of both white arsenic and calcium arsenate. Usually the arsenic season extends from November to March but this year there has been an abnormal demand from the insecticide consuming districts, particularly in the cotton growing regions. The use of calcium arsenate in combating the boll weevil was largely brought about through governmental research and it is perhaps natural that the cotton growers have been appealing to the federal and state governments for help in meeting the situation caused by the shortage of these materials. The Georgia State Department of Agriculture is reported to have created a revolving fund with which to buy calcium arsenate and distribute it at cost to farmers in that state. A contract secured early in the year at 9c. per lb. has been disposed of and the supply is said to be running short. Farmers in many of the other states are reported to be facing as serious a situation and this scarcity is already evident in the arsenic market.

While the abnormal demand from the insecticide trade is doubtless the principal cause for the arsenic shortage, there are a number of contribut-

April, 1918 (high)	286
April, 1921 (low)	140

For the third consecutive week this index number has declined. This is probably attributable to the seasonal inactivity of the chemical market rather than to any broad market movement. Lower prices for caustic soda and linseed and cottonseed oils were responsible for this week's decline.

ing factors. The reduced output of copper (and consequently of domestic byproduct arsenic), and the decrease in imports from Mexico and Japan are most important. Neither Germany nor England have been a factor in the arsenic market for at least 6 years.

Production and Consumption

The maximum annual consumption of white arsenic in the United States was in 1920 when it was estimated that approximately 15,000 tons were used. In 1921 this dropped to not more than 9,000 tons. It is difficult to estimate the amount of white arsenic consumed in the United States because of its wide variance—from 3,400 tons in 1904 to 15,000 in 1921. The following figures, estimated by a leading factor in the industry, are believed to be as accurate as are available:

	Tons
By the glass manufacturers	2,500 to 3,000
Sheep and cattle dips, approximately	1,500
For dyes, pharmaceutical and other purposes, approximately	500
In the manufacture of lead and calcium arsenates, insecticides, and weed killers, approximately	5,000 to 9,000

Prior to 1914 by far the larger share of arsenic used in this country was imported. From 1901 to 1910 the United States produced only an average of about 975 tons, while imports averaged 4,235 tons. Production from 1911-1920 is given by the Geological Survey as follows:

Year	Quantity (Short Tons)	Value
1911	3,132	$73,408
1912	3,141	190,757
1913	2,513	159,236
1914	4,670	313,147
1915	5,498	302,116
1916	5,986	555,187
1917	6,151	1,118,313
1918	6,323	1,213,000
1919	6,029	.....
1920	11,500	.....

Conflicting Views on Labor Troubles

Economists, as well as doctors, often differ in their diagnostics. Industrial ills are now a fitting subject of study and they are being approached from many different angles. Two outstanding groups of economic students have recently offered views on the labor situation, which at first glance might seem to be at considerable variance. Underlying both, however, is the firm belief that present labor difficulties are but a temporary deterrent to continued industrial progress.

In the following paragraph quoted from a recent letter of the Harvard Economic Service, a striking parallel is shown by a comparison of industrial conditions in the fall of 1919, with those of the present.

> Labor trouble is the darkest cloud upon the present business horizon. Seldom has the country ever faced as many serious strikes as at the present time. The situation in this respect bears a strong resemblance to the fall of 1919. Numerous strikes at that time—those in the steel and soft coal industries being the most important—restricted output at a time when it otherwise would have expanded rapidly. * * * It will not be surprising if this episode is repeated in 1922. As yet, however, current output has manifested little retardation. Unless the existing labor difficulties are of unusual duration or spread to other industries, like interstate transportation, no general loss of industrial pace is to be expected.

Roger Babson, on the other hand, points out in one of his recent barometer letters that there is an evident tendency at the present time to overestimate the significance of labor difficulties. "The labor situation is by no means as bad as it seems," he declares. "The coal and railroad strikes make spectacular news and, of course, are important. Taken as a whole however, the labor situation is very much improved. At present we have a few large strikes, whereas during the last few years we have had a number of small strikes."

Mr. Babson then refers to a chart "which shows that in actual number there are fewer strikes in progress than during 1917, 1918, 1919 or the greater part of 1920. Considering that spring and summer are the 'strike seasons' the current year's record is the most favorable since 1915."

The New York Market

New York, July 24, 1922.

Trading in the chemical market during the past week has been unusually quiet, due presumably to adverse conditions existing in several leading industries. Difficulties on the railroads, tariff reversals and labor troubles have added to the severe strain on the chemical industry. The chief demand at present is for small lots, with larger quantities commanding little attention. The export situation for alkalis has not shown any unusual strength and trading has been along very limited lines. The market in several commodities has uncovered some strong features, with white powdered arsenic and sulphate of ammonia showing most improvement. Manufacturers of lime acetate announced another increase effective July 22. It is expected that both acetone and acetic acid will be advanced proportionately.

General and Special Chemicals

Acetate of Lime—Factors have again advanced prices on this commodity, due to the increasing demand and the curtailed production. The new prices are around $2.35 per 100 lb. for carload quantities.

Ammonium Sulphate—Spot supplies are exceedingly scarce with sellers offering only small lots. A good export inquiry has reached this market and prices ranged from $3.55@$3.60 per 100 lb., f.a.s. in double bags.

Arsenic — The prime white material is much firmer on spot and leading dealers were not anxious to book business at under 8c. per lb. Demand from the insecticide trade continues unabated. Foreign shipments have been delayed as much as three months, causing a pronounced shortage in the spot market. Prices ranged from 8@8¼c. per lb.

Barium Chloride — Spot goods were rather easy during the interval and sellers named prices around $90@$95 per ton. Shipments from abroad were held at $85 per ton, c.i.f. New York.

Bichromate of Potash — Round lots were sold down to 9½c. per lb. Smaller transactions were heard up to 10c. per lb. Buying has been very quiet in this product during the past week.

Caustic Soda — Export business has been somewhat slow, with a few sales noted at $3.55 per 100 lb. The general range is from $3.55@$3.60 per 100 lb., f.a.s. Domestic material is moving moderately at $3.75 per 100 lb. ex store.

Hyposulphite of Soda—Domestic factors report sales for regular crystals at 3c. per lb. Pea crystals are quoted at $3.50@$4 per 100 lb. The demand is fair.

Nitrite of Soda — There has been very little improvement in demand during the past few weeks in this product. Resale lots are being quoted at 8@8½c. per lb. Producers' figures are unchanged at 9c. per lb., f.o.b. works.

Prussiate of Potash — The yellow variety was fractionally lower at 31½c. per lb. for limited quantities. Shipments from abroad are held around 30½c. per lb. The red material is unchanged at 90c. per lb.

Soda Ash—Leading sellers have not changed their prices and quote $1.75 per 100 lb. for single bags, in carload lots, and $1.90 in barrels. Producers report a firm market for contract requirements.

Coal-Tar Products

There have been no unusual features in this market during the past week. Business has been moderate with the general demand for small lots. Lower prices were reported for dinitrochlorbenzene and alpha naphthylamine. Crude products have continued to show strength with no special price changes reported.

Alpha Naphthylamine — Inquiries have been heard from various consuming quarters and the market is in a very promising condition. Small lots are moving at 28@30c. per lb.

Aniline Oil—Producers report a fair demand, with quotations heard around 14c. per lb. The market has shown a steady tone of late and any buying improvement will advance present levels.

Benzaldehyde—The demand is somewhat active and producers are satisfied with the amount of passing business. First hands report the U.S.P. grade at $1.25 per lb. and technical at 60@70c. per lb.

Beta Naphthol — Producers are not inclined to shade their prices and quote 24c. per lb. as the low figure. The movement, in general, is rather quiet, with competition keen for any new business. Some small lot sales through second hands were transacted at prices as low as 22c. per lb.

The St. Louis Market

ST. LOUIS, MO., July 20, 1922.

There have been no important developments during the past two weeks in this market and the actual business transacted has been on a par with the corresponding period of last month. The usual summer lull has not gained its full sway as in past years. Price changes have been very few and the general tone of the market is firm. Imports have not been so numerous, with the result that there has been a very heavy demand for certain domestic commodities. One of the groups which is very prominent at this time is the insecticides, and also the chemicals used in their manufacture.

GENERAL AND SPECIAL CHEMICALS

The alkali market has recently been thrilled with the oft repeated post war cry, "Open prices openly arrived at." Two of the largest manufacturers having adopted the novel scheme of displaying their complete price schedules. These prices for St. Louis are as follows: *Soda ash* in bags, \$2.19 per 100 lb.; in bbls., \$2.43 per 100 lb. for 58 per cent light. *Caustic soda*, solid, \$3.90, flake \$4.39, basis 76 per cent. *Bicarbonate of soda*, bbls., \$2.35; kegs, \$2.60 per 100 lb. These prices are for truck load quantities f.o.b. buyers' door. Smaller quantities sell at a reasonable advance. We believe that these prices will be generally adhered to. *Sal soda* is rather quiet with prices steady.

The whole situation on heavy mineral acids is very good today with several advances in *sulphuric*, also in *hydrochloric*. The *citric-acid* situation has eased and spot stocks are more easily obtainable. *Oxalic acid* continues to stiffen, with makers quoting from 2½@16c. per pound, occasional buyers having difficulty in locating spot stock. *Tartaric acid* while doing very well a month ago has slowed up a trifle. There is still a scarcity of *white arsenic* with the demand good and the market strong, prices being quoted at 8c. f.o.b. New York. *Carbon bisulphide* continues to be in heavy demand from the agricultural centers. Due to the present condition of the steel mills there is again a scarcity of *copperas*, and quotations are firm. *Glycerine* has taken another sharp advance and is firm at 15½c. in drums with producers completely in command. As a matter of fact they are somewhat reluctant about new business and are apparently sold to capacity for some time to come. While there is a regular but limited demand for *potassium cyanide*, the smallness of stocks is not noticeable. *Photographic chemicals* are showing a steady improvement, and a nice volume of business is being done. *Sulphur* is still going at about the same pace with no noticeable change in price or volume of movement. *Zinc dust* has been very quiet, but in sympathy with spelter has recently advanced from ½ to ¾c per pound. Stocks of *zinc spelter* have been reduced over 50 per cent during the last thirty days, and actual supplies available at this time are less than thirty days. The market is very strong and is around \$5.80 per 100 lb. *Zinc sulphate* continues to be very strong and has sharply advanced, now being quoted \$2.75@2.85 per 100 lb. carload lots f.o.b. St. Louis.

VEGETABLE OILS AND NAVAL STORES

Turpentine went as low as \$1.21 in single barrels, but is now on another rebound and commands \$1.32 per gallon. *Linseed oil* is very quiet and price remains about as previously reported. Considerable spot business is now being done, but it is all a "hand to mouth" transaction. *Castor oil* is again stepping up, another one-half cent having been added to the old price of 12¾c. A good volume of business is being done on this item and further advances may come along at any time.

PAINT MATERIALS

This is the dull season between the spring and fall rush and aside from general routine purchasing, very little is going on. Several of the prominent paint grinders are taking advantage of low freight rates on Mississippi barge lines from New Orleans and are having carloads of *ochre* shipped direct from France via New Orleans.

The Iron and Steel Market

PITTSBURGH, July 21, 1922.

The dominant factors in the iron and steel situation are transportation conditions and the coal strike. Following the congestion that began about the middle of June on the railroads serving non-union coal districts in West Virginia and Kentucky came the strike of railroad shopmen July 1, and transportation conditions in many sections are now decidedly poor. Supplies of non-union coal to steel mills and by-product coke plants, particularly in Ohio, Western Pennsylvania and the Buffalo district, are greatly curtailed, while the movement of finished steel products is beginning to grow difficult. Even the movement of scrap is affected in some cases.

This week's developments at Washington in the coal matter make it the present outlook that the national organization of coal miners will be shorn of much of its power but that there will be a long and difficult struggle, during which coal will be scarce and high priced.

DECLINE IN STEEL PRODUCTION

The steel market is a matter of tonnage and price. As to tonnage, production has already decreased slightly, not enough to make much difference at the moment, but enough to show that the rate of production is decreasing, after having increased almost constantly for six months. The sharp increases were in the first three months of the year, with more moderate increases in April and May, followed by a merely perceptible increase in June, the rate in June being about 80 per cent over the rate in December. Since then the rate has decreased slightly, but possibly by as much as 5 per cent. With the present trends, there will be a greater decrease in the next fortnight.

The price of steel is another matter. It requires coal and transportation facilities to consume steel as well as to produce steel, a fact that is occasionally overlooked. Thus far there has been no definite sign that steel consumption is materially reduced, but there are distinct possibilities that it may be.

While the actual rate of steel consumption cannot be scrutinized closely, the attitude of steel buyers can be observed. This attitude has undergone some change. There is somewhat more eagerness to buy prompt lots, not in large quantities but in moderate sized lots, and there is willingness to pay extra prices. Some steel products, such as butt weld pipe, are being bought in carload lots from warehouse at regular warehouse prices, representing a differential over prices for mill deliveries that would be a stupendous advance if written into the mill price. On the other hand, buyers are showing a strong disinclination to commit themselves on purchases for delivery in the late months of the year. The turnover in far-forward deliveries is very light. Very probably the mills would not care to sell freely for such deliveries but the market shows that they do not have the opportunity now, as they did have a few weeks ago.

STEEL AND IRON PRICES

Basis prices are practically unchanged and there is little if any disposition on the part of mills to advance them, evidently by reason of fear that advances would merely invite a reaction later on. Prompt deliveries are higher in some cases, particularly in bars, shapes and plates, which have been going at prices as high as 1.80c. or 1.90c., the basis price, for late delivery, remaining at 1.60c. Sheets are moving less at premium prices than formerly, and some mills formerly demanding a premium for shipment from stock are now offering stock sheets at basis prices, 2.40c. for blue annealed, 3.15c. for black and 4.15c. for galvanized.

The \$2.50 price on nails instituted by independents about the middle of April has practically disappeared, the regular market being \$2.40; the price the American Steel & Wire Co. has adhered to. Demand is better than usual at this time of year. Wire fence has been stimulated somewhat by the recent reduction of 2½ points.

Pig iron continues dull as to actual turnover. Consumers are not disposed to take hold, despite the prospect that production will decline considerably in the next few weeks on account of coke shortage. The local market is quotable at \$25 for Bessemer and \$24 for basic and foundry, both basic and foundry being a shade lower than the average market price ruling in May and June. At present, coke prices are far below cost of production.

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.14 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.50 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.23 — .26
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.21 — .22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Dipnenylamine	lb.	.59 — .65
H-acid	lb.	.85 — .95
Meta-phenylenediamine	lb.	.95 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.00 — 1.20
Naphthalene crushed, in bbls.	lb.	.06 — .06¼
Naphthalene, flake	lb.	.06¼ — .07
Naphthalene, balls	lb.	.07½ — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35

itro-toluene	lb.	.15 —	.17
-W acid	lb.	1.15 —	1.30

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Benson Paint & Varnish Co., 2317 1st Ave. recently organized with a capital of $50,000, is planning for the installation of additional equipment for the manufacture of its regular line of paint products. K. Y. Benson is president.

MONTGOMERY—The American Cotton Oil Co. has preliminary plans in progress for the construction of a new building at its plant on Decatur St., near Pollard St., estimated to cost about $13,000.

MOBILE—The Fish Products Corp., recently organized with a capital of $50,000, has acquired property on the Bayou la Batre as a site for the erection of a new plant for the manufacture of fertilizer products. The initial works will be equipped for a capacity of about 10 tons of commercial fertilizer daily. The company is headed by W. B. Jones, Biloxi, Miss., and John E. Rolston, Coden, Ala.

California

SANTA PAULA—The Standard Oil Co. of California, San Francisco, has plans under way for the construction of a new oil distributing plant. A local site has been acquired. The plant will consist of a number of 1-story buildings.

PITTSBURG—Following a merger of the Columbia Steel Co., Market St., San Francisco, and the Utah Coal & Coke Co., operating in Carbon and Iron Counties, Utah, the new company, to be known as the Columbia Steel Corp., capitalized at $15,000,000, has extensive plans under way for expansion. It is proposed to enlarge the present mill at Pittsburg as well as the steel foundry at this location; the Utah properties will also be developed. The work is estimated to cost in excess of $1,500,000.

SAN LUIS OBISPO—The Associated Oil Co. has commenced the construction of a new distributing and industrial plant on the Islay Road. It will consist of a number of 1-story buildings, with tanks, etc., estimated to cost about $35,000.

LOS ANGELES—Kay & Brunner, 2714 Frederick St., operating a foundry, have filed plans for the erection of a new 1-story addition.

Connecticut

HARTFORD—The Capital Glass Co., 14 Chapel St., has filed plans and commenced the erection of a new addition, estimated to cost about $29,000.

Florida

DAYTONA—A new company is being organized by L. E. and L. N. Treadaway, Daytona, to construct and operate a local plant for the manufacture of insect powders and other chemical specialties. The company will be capitalized at $85,000 and it is said that the new plant will cost close to $40,000, including equipment.

Indiana

EVANSVILLE—The Southern Indiana Gas & Electric Co. has commenced the construction of a new gas-retort building, in connection with a number of gas plant improvements, estimated to cost close to $500,000.

EVANSVILLE—William S. Baerich and associates have acquired the local plant of the Stronghold Tire & Rubber Co., from the receiver. The factory was commenced a number of months ago but was never completed. The new owners are said to be planning to reorganize the company, finish the plant erection, and install equipment for the manufacture of tires and other rubber goods.

Illinois

JOLIET—The Standard Wall Paper Co., Hudson Falls, N. Y., has awarded a contract to the Austin Co., 208 South LaSalle St., Chicago, for the construction of a new 1-story plant on East Washington St., 60x100 ft., estimated to cost approximately $75,000, including equipment. Winfield A. Huppuch is president.

GRANITE CITY—The National Enameling & Stamping Co., 411 5th Ave., New York, N. Y., manufacturer of enameled ware, has plans nearing completion for the construction of an addition to its local plant, comprising 6 new buildings, estimated to cost approximately $1,500,000, including equipment. George W. Niedrinhous is president.

EAST ST. LOUIS—The Obear-Nester Glass Co., 25 North 2nd St., St. Louis, Mo., has commenced the construction of its proposed new local plant at Broadway and 22nd St., to be 1-story, 150x230 ft. and estimated to cost about $40,000. The company specializes in the manufacture of glass bottles and containers.

CHICAGO—The Chicago Butchers' Calf Skin Association, 3208 South Robey St., is taking bids and will soon award contract for the construction of a 3-story addition to its fertilizer manufacturing plant at location noted, 24x140 ft., estimated to cost about $50,000. H. C. Christensen, 7258 Union Ave., is architect. William Haffel is president.

ROCKFORD—The Rockford Malleable Iron Works, Inc., has awarded a contract to The Austin Co., 208 South LaSalle St., Chicago, for the construction of a new 1-story foundry, 150x200 ft., estimated to cost about $125,000, including machinery.

Kentucky

ASHLAND—The Indian Refining Co., 27th St. and Greenup Ave., has preliminary plans under way for the construction of an addition to its local oil plant, to consist of a number of 1-story buildings.

LOUISVILLE—The Peaslee, Gaulbert Co., 413 Main St., manufacturer of varnishes, wood finishes, etc., has commenced excavations for its proposed plant addition at 15th and Lytle Sts., to be 1-, 2- and 3-story, estimated to cost about $100,000, including equipment. Alterations and improvements will be made also in the present factory. D. X. Murphy & Brothers, Louisville Trust Bldg., are architects.

Maryland

BALTIMORE—The Board of Directors, Johns Hopkins University, has plans nearing completion for the construction of a 4-story chemical laboratory at the institution, 200x200 ft., estimated to cost about $500,000. Carrere & Hastings, 52 Vanderbilt Ave., New York, N. Y., are architects; Charles L. Reeder, 916 North Charles St., Baltimore, is engineer.

BALTIMORE—The Oil Products Co., 304 North Holiday St., manufacturer of lubricating oils, greases, and chemical specialties, recently reorganized with a capital of $35,000, has plans under way for enlargements in its 3-story plant for considerable increase in capacity. J. G. Platt is president; A. L. Kibler is vice-president and chemical director.

BALTIMORE—A 1-story foundry, estimated to cost about $25,000, will be constructed at the new plant of the Republic Boiler & Radiator Co., Union Ave, Woodberry district.

HAGERSTOWN—The Security Cement & Lime Co. plans for the installation of a new tube mill at its plant. Inquiries are out for used equipment in first class condition.

Michigan

DEARBORN—The Ford Motor Co., Highland Park, Mich., has plans under way for the construction of a 1-story laboratory building on local site, 200x800 ft. estimated to cost approximately $500,000, including equipment. It will be used for steel and steel alloy testing, and other general laboratory service.

Minnesota

CLOQUET—The Northwestern Paper Co. has awarded a contract to Siems, Helmers & Schaffner, Inc., 514 Guardian Life Bldg., St. Paul, Minn., for the construction of a 2-story sulphite pulp mill, 200x500 ft., to cost close to $500,000, including machinery. George F. Hardy, 209 Broadway, New York, N. Y., is engineer.

Missouri

JOPLIN—The Wilhoit Refining Co. has plans under way for extensions and improvements in its local oil refinery to cost about $75,000.

New Jersey

BAYONNE—The International Nickel Co., Oak and Hobart Aves., has filed plans for the construction of an addition to its local plant to cost about $15,000.

New York

PEEKSKILL—Fire, July 11, destroyed two of the buildings at the local plant of the Fleischmann Yeast Co., with loss estimated at about $125,000, including equipment. It is said that the plant will be rebuilt. Headquarters of the company are at 701 Washington St., New York, N. Y.

North Carolina

NEWTON—The Newton Oil & Fertilizer Mill, Inc., has preliminary plans under consideration for the construction of a new local plant for the manufacture of commercial fertilizers. S. D. Hauk is head.

FOREST CITY—The Forest City Oil Mill Co., manufacturer of cotton-seed oils, has plans nearing completion for the construction of a new local plant, estimated to cost about $90,000. Of this amount, approximately $65,000 will be expended for equipment.

Ohio

AKRON—The American Vitrified Product Co. has filed plans and will commence the immediate erection of an addition to its plant to replace a structure recently destroyed by fire.

AKRON—The Firestone Tire & Rubber Co. will soon commence the installation of equipment in a new building at its plant completed a number of months ago and heretofore unoccupied. It will be used for the manufacture of steel specialties, including rims etc., for automobile tires.

BARBERTON—The Lambert Tire & Rubber Co. will install equipment at once at its plant, to double the present capacity.

Oklahoma

OKLAHOMA CITY—The Apco Refining Co., Colcord Bldg., recently incorporated with a capital of $100,000, has selected a local site and has plans in preparation for the construction of a new oil refining plant with initial output of about 1,200 bbl. per day.

PONCA CITY—The 101 Ranch Co. is reported to be planning for the rebuilding of its tanning plant, including power house, destroyed by fire July 6, with loss estimated at about $50,000, including equipment.

Pennsylvania

STROUDSBURG—Fire, July 14, destroyed the plant of the Nitroloid Corp., manufacturer of celluloid and other compositic products, with loss estimated at about $250,000 including equipment. It is said that the plant will be rebuilt.

JACOBS CREEK—The U. S. A. Drug Chemical Co., Jacobs Creek, has plans under way for the construction of a new 3-story plant on local site, 72x125 ft., estimated to cost about $150,000, including equipment. Peter R. Rossello 406 Congress Bldg., Detroit, Mich., is architect.

READING—Orr & Sembower, Inc., Millmont, near Reading, operating a metal working plant, is planning for the rebuilding of the portion of its brass foundry, recently destroyed by fire. The estimated loss has not been announced.

PHILADELPHIA—E. I. duPont de Nemours & Co., manufacturers of paints, varnishes, etc., have filed plans for the construction of a 1-story addition to their local plant at 3500 Grays Ferry Road, estimated to cost about $15,000.

PITTSBURGH—E. A. Campbell has acquired the plant and equipment of the Eagel Paint & Varnish Co., Galveston Ave., from Elliott Frederick, trustee. The plant is located on a site 150x270 ft., and was secured for a consideration said to be $5,170. The new owner is said to be arranging for a reorganization of the company and the continuance of the plant in operation.

PHILIPSBURG—Thomas J. Lee and associates are perfecting arrangements for the reorganization of the Nickel Fabricating Co. and the operation of the local plant recently acquired under bankruptcy pr

eedings. The plant has been idle for bout six months past. The new company ill make repairs and improvements to the quipment and plan to place the works in ervice at an early date.

Tennessee

CHATTANOOGA—The Scholze Soap & Fertilizer Co., recently organized with a capital of $150,000, has preliminary plans under way for the construction of a new plant on local site for the manufacture of soap roducts. It is estimated to cost about 100,000, including machinery. Henry cholze and J. N. Kline, head the company.

Texas

DALLAS—E. L. Flippen, heretofore vice-resident of the Planters' Cotton Oil Co., nd Hugh E. Prather have acquired the ocal plant of the company, under bankuptcy proceedings, for a consideration of 99,000. The mill is located in the Breezy ill section and was constructed a number of years ago, at a cost said to be 400,000. The new owners will reorganize he company and will make extensions and mprovements to the plant. It is expected o have the mill ready for production early n the fall.

SAN ANTONIO—The Ideal Mfg. Co., recently organized, has plans in preparation or the construction of a 1-story plant on ocal site, 60x175 ft. for the manufacture f polishes, enamels, etc. E. D. Nolan is reasurer.

CROSS PLAINS—The Bristow Refining Co. completing the construction of the first nit of its new local oil refining plant, and lans to place the mill in service at an arly date. It will have a capacity of bout 500 bbl. per day. It is proposed to onstruct additional plant units in the near uture.

Virginia

RICHMOND—The Fish Guano Co. has acuired property at Fulton, near Richmond, nd plans for the constructon of a new 1-tory plant, 105x200 ft., for the manufacture of fertilizer products. It will have an initial capacity of about 25,000 tons of material per annum, and is estimated to cost about $55,000, with machinery. Walter C. Hill is president.

West Virginia

WHEELING—The Wheeling Oxygen Co., 1130 Market St. has commissioned the Industrial Engineering Co., Park Bldg., Pittsburgh, Pa., to prepare plans for the construction of a new plant on 16th St., Warwood, near Wheeling. It will be used for the manufacture of commercial oxygen, and is estimated to cost in excess of $50,000.

SHINNSTON—The Alley Glass Co., recently organized, has acquired a local building for the establishment of a new plant for the manufacture of cut glass products. L. E. Alley is president and general manager; Paul E. Tetrick is treasurer.

LUMBERPORT—The Mound City Glass Co. has commenced the construction of a new finishing department at its plant and will make other extensions and improvements to double, approximately, the present capacity. It is proposed to increase the working force by about 150 men upon completion.

Canada

NEW WESTMINISTER, B. C.—The Westminster Paper Co., affiliated with the Interlake Tissue Paper Co., Merritton, Ont., has preliminary plants in progress for the construction of a new mill on the Frazier River for the manufacture of tissue and other light-weight papers. It is said that the plant will cost in excess of $200,000.

MONTREAL, QUE.—The British Empire Steel Corp. is reported to be planning for the construction of a new steel mill, to cost in excess of $10,000,000. The work will comprise new open hearth furnaces, blooming mills, as well as improvements to present blast furnaces. A number of buildings at the present works will also be remodeled and improved, and new equipment installed.

New Publications and Books

"The Future Independence and Progress f American Medicine in the Age of Chemtry." A report by John J. Abel, Carl L. lsberg, Raymond F. Bacon, F. R. Eldred, eid Hunt, Treat B. Johnson, Julius Stiegz, F. O. Taylor and Charles H. Herty. ublished by the Chemical Foundation, ew York.

Beiträge zu Einer Kolloidchemie des ebens (Biologische Diffusionen). By Dr. aphael Ed. Liesegang. Published by Verg von Theodor Steinkopff, Dresden and eipzig, Germany.

The Imperial Mineral Resources Bureau, ondon, England, has issued pamphlets on old, copper, tin and platinum and allied etals. All of these are for the war period om 1913 to 1919.

The Department of Scientific and Inustrial Research, London, has issued Bultin No. 6 on the Electrodeposition of on. By W. E. Hughes.

The University of Illinois has issued ulletin No. 128, on "The Ignition Temerature of Coal," by Ray W. Arms, and ulletin No. 129, on "An Investigation of ie Properties of Chilled Iron Car Wheels," y J. M. Snodgrass and F. H. Guldner.

The U. S. Department of Agriculture has sued Bulletin No. 983, on "The Manufacre of Ethyl Alcohol From Wood Waste," y F. W. Kressmann, and Bulletin No. 57, on "The Chaulmoogra Tree and Some elated Species," by Joseph F. Rock.

The Scientific and Industrial Research ouncil of Alberta has issued its second nnual report.

The Bureau of Foreign and Domestic ommerce has issued Trade Information ulletin No. 11, "The Steel-Making Facili-s of Great Britain" by H. B. Allin Smith nd Trade Information Bulletin No. 31, "Markets for Chemicals in the Netherands, East Indies and British Malaya" by hn A. Fowler.

New U. S. Geological Survey Bulletins: ome Field Tests and an Assay of Texas otash Salts" by George Steiger. This imeographed report can be obtained on pplication to the Survey office in Washgton. The methods described are for entification and analysis of the mineral lts with special reference to the examinaon of the types of mineral found in the estern Texas fields. The instruction for ld methods are given in elementary form that those with little or no previous aining in chemistry will be able to carry em out. Other bulletins are I: 1, "Cadium in 1921," by C. E. Siebenthal and A. Stoll (Mineral Resources of the U. S., 1921, Part 1) published April 10, 1922; I: 2, "Gold, Silver, Copper, Lead, and Zinc in the Eastern States in 1921." by J. P. Dunlop (Mineral Resources of the U. S., 1921, Part I) published May 12, 1922; I: 23, "Quicksilver in 1920," by F. L. Ransome, with a supplementary bibliography by Isabel P. Evans (Mineral Resources of the U. S., 1920, Part I) published March 27, 1922; I: 25, "Lead and Zinc Pigments and Salts in 1920," by C. E. Siebenthal and A. Stoll (Mineral Resources of the U. S., 1920, Part I) published April 26, 1922; I: 26, "Copper in 1920" (General Report) by H. A. C. Jenison (Mineral Resources of the U. S., 1920, Part I) published May, 16, 1922; II: 2, "Graphite in 1921," by L. M. Beach (Mineral Resources of the U. S., 1921, Part II) published June 5, 1922; II: 3, "Peat in 1921," by K. W. Cottrell (Mineral Resources of the U. S., 1921, Part II) published June 6, 1922; II: 29, "Mica in 1920," by B. H. Stoddard (Mineral Resources of the U. S., 1920, Part II) published April 12, 1922.

New Bureau of Mines publications: Bulletin 200, "Evaporation Loss of Petroleum in the Mid-Continent Field," by J. H. Wiggins; Bulletin 207, "The Analytical Distillation of Petroleum and Its Products," by E. W. Dean, H. H. Hill, N. A. C. Smith and W. A. Jacobs; Tech. Paper 258, "Production of Gasoline by Cracking Heavier Oils," by E. W. Dean and W. A. Jacobs; Tech. Paper 263, "Design and Operation of a Low-Pressure Absorption Plant," by W. P. Dykema and A. A. Chenoweth; Tech. Paper 268, "Preparation and Uses of Tar and Its Simple Crude Derivatives," by W. W. Odell; Tech. Paper 298, "Methods for Testing Petroleum Products;" Tech. Paper 305, "Specifications for Petroleum Products adopted by the Interdepartmental Petroleum Specifications Committee."

New Bureau of Standards publications: Scien. Paper No. 432, "An Improved Method for Preparing Raffinose," by E. P. Clark; Scien. Paper 433, "Thermal Expansion of a Few Steels," by Wilmer Souder and Peter Hidnert; Scien. Paper 434, "Electromotive Force of Cells at Low Temperatures," by G. W. Vinal and F. W. Altrup; Scien. Paper 435, "Metallographic Etching Reagents," by Henry S. Rawdon and Marjorie C. Lorentz; Scien. Paper 436, "Interference Methods for Standardizing and Testing Precision Gage Blocks," by C. G. Peters and H. S. Boyd; Scien. Paper 437, "The Solubility of Dextrose in Water," by Richard F. Jackson and Clara Gillis Silsbee; Tech. Paper 210, "The Redwood Viscosimeter," by Winslow H. Herschel.

The smoke investigation of the Mellon Institute has Bulletin No. 10 in press. This publication, which is entitled "Recent Progress in Smoke Abatement and Fuel Technology in England," presents the results of an investigation by Robert J McKay, an industrial fellow of the Institute.

BOOKS

AMERICAN RESEARCH CHEMICALS. By *Clarence J. West.* National Research Council, Reprint and Circular Series No. 35, pp. 37. Price, 50c. The research chemist and the purchasing agent in search of unusual and comparatively unknown chemical compounds will find this compilation extremely valuable. The pamphlet is the report of the Council's committee on research chemicals, of which W. D. Collins is chairman and C. J. West secretary. The subject matter is divided into four parts, viz.: A list of the 80 manufacturers of fine chemicals, the names of approximately 1,800 research chemicals with numerical reference to their manufacturers, 500 biological stains, indicators and their makers' numbers and finally, the principal hydrogen-ion indicators, the index number of the firms making them and a chart showing their *pH* ranges.

MEXICAN YEAR BOOK, 1920-1921. By *Robert Glass Cleland, Ph.D.* Los Angeles: Mexican Year Book Publishing Co., cloth, 6x9 in.; pp. 524. Price, $7.50. Americans desirous of unbiased and systematized information concerning Mexico will find this book unusual in that it has no official Mexican patronage. In addition to authoritative chapters on geography, transportation, commerce, natural resources, etc., the book contains an appendix of practical suggestions for business travelers in Mexico and gives details concerning postal and tariff regulations, the recent colonization decree and the treaties now in force between Mexico and the United States. It also contains a bibliography of works on Mexico. Three maps show the political divisions, principal cities, lines of communication, mining centers and the Panuco-Tuxpam oil fields.

WORLD METRIC STANDARDIZATIONS AN URGENT ISSUE. Compiled by *Aubrey Drury* and collaborators. Published by World Metric Standardization Council, San Francisco, Cal. 524 pp. Price $5. Herbert Hoover is responsible for the statement: "Standardization is an outstanding necessity in the mind of every engineer desirous of the advance of industry and commerce. There is no field where more constructive work can be accomplished in this direction of national efficiency of the whole gamut of production and distribution than in the field of standards." Engineers who are willing to accept this generalization of Secretary Hoover will find much of interest in Mr. Drury's exhaustive compilation, for this volume deals with the "master standards" of the world—the three metric units—meter, liter, gram. The book urges that the units of weights and measures of the United States and the British commonwealths be brought into accord with these invariable standards, for when this advance is achieved, practically the entire world will be upon the uniform metric basis. The compilation of this book is the result of a number of years of intensive study. Over 30,000 letters and papers on the metric movement had been gathered into the files of the World Standardization Council and in addition the compilers drew largely on material in the files of the American Metric Association, the British Decimal Association and a number of other such organizations. The work is a valuable storehouse of information to all who are interested in the progress of metric standardization.

"SUMMARY OF TARIFF INFORMATION, 1921" is the title of a 1,600-page volume just issued by the Tariff Commission, Washington, D. C. Copies may be obtained from the Superintendent of Documents, Government Printing Office, at $1.25.

"DUST EXPLOSIONS" is the title of a new book, by *David J. Price* and *Harold H. Brown*, assisted by *Hylton R. Brown* and *Harry E. Roethe*, just published by the National Fire Protection Association, Boston, Mass., with permission of the U. S. Department of Agriculture. Price, $3. The book contains the results of the dust explosion investigations of the Bureau of Chemistry, U. S. Department of Agriculture and should be of value in the prevention of dust explosions and the reduction of losses to life, foodstuffs and property in the industrial plants of the United States and Canada.

ELEKTRISCHE BEHANDLUNG VON GASEN. By *Henri Silbermann.* Published by Dr. Max Jänecke Verlagsbuchhandlung, Leipzig, Germany.

New Companies

THE TURLINGTON CHEMICAL CO., 339 Equitable Bldg., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical by-products, soaps, etc. The incorporators are Randall A. Turlington, Philander B. Briscoe and Willis R. Jones.

THE COLREX MFG. CO., New York, care of C. E. Toney, 184 West 135th St., representative, has been incorporated with a capital of $25,000, to manufacture polishes and kindred specialties. The incorporators are J. E. Blackwell, D. and J. C. Doles.

THE RELIANCE TILE & FAIENCE CO., Perth Amboy, N. J., has been incorporated with a capital of $300,000, to manufacture tiles, ceramics, and kindred products. The incorporators are Fred Keck, George J. Janovsik and N. F. Herron, 107 Fayette Street, Perth Amboy.

THE NEHOIDEN OIL CO., Boston, Mass., has been incorporated with a capital of $100,000, to manufacture refined oil products. M. William Lawlor is president and James Keltie, 83 Warren Street, Needham, Mass., treasurer.

THE SUPERIOR CHEMICAL PRODUCTS CORP., 303 West Chicago Ave., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical by-products. The incorporators are Douglas G. Logan, H. J. Logan and Claude H. Pratt.

THE UNIVERSAL PAPER GOODS CO., Los Angeles, Cal., care of Kimpton Ellis, 626 Washington Bldg., representative, has been incorporated with a capital of $20,000, to manufacture paper specialties. The incorporators are G. R. Allenson, L. E. Bartels and H. D. Allenson, all of Los Angeles.

THE BURNOT FIREPROOFING PRODUCTS OF BALTIMORE, INC., 207 West Calvert St., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture fireproof paints and other kindred fireproofing products. The incorporators are William R. Semans, Henry L. D. Standford, Jr. and F. Fulton Bramble.

THE GREAT EASTERN GALENA SILVER, LEAD & ZINC CO., Pottsville, Pa., care of the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia, Pa., representative, has been incorporated under Delaware laws with a capital of $400,000, to operate zinc, lead and other metal refining plants and properties. The incorporators are Miles E. Reinhart, Palmerton, Pa.; Jacob Brewer, Hazleton, Pa., and C. Crossman, Pottsville.

THE BAYWAY COLOR WORKS, INC., 36 East State St., Trenton, N. J., has been incorporated with a capital of 5,000 shares of stock, no par value, to manufacture colors, chemicals, etc. The incorporators are Edward C. Georges, Louis F. Menage and William Campbell.

THE ACOMA CHEMICAL CO., Clayton, Mo., has been incorporated with a capital of $15,000, to manufacture chemicals and chemical byproducts. The incorporators are Moses Leon, J. F. L. and B. M. Zingre, all of Clayton.

THE BRANFORD BRASS FOUNDRY, INC., Branford, Conn., has been incorporated with a capital of $50,000, to manufacture brass, bronze and other metal castings. The incorporators are F. A. Ellis, H. A. Cox and A. V. Neilson, all of Branford.

THE STEVENS & THOMPSON PAPER CO., North Hoosick, N. Y., has been incorporated with a capital of $1,500,000, to manufacture paper products. The company will comprise a consolidation of the Stevens & Thompson Co., and the Walloomsac Paper Co. Frank L. Stevens, North Hoosick, is the principal incorporator and represents the company.

THE NUEVA OIL CO., Laredo, Tex., has been incorporated with a capital of $40,000, to manufacture petroleum products. The incorporators are O. W. and W. T. Killam, and R. F. Peck, all of Laredo.

THE METROPOLITAN PETROLEUM CO., Long Beach, Cal., has been incorporated with a capital of $200,000, to manufacture petroleum products. The incorporators are Albert Stephens, Claude C. Sumter and F. E. Lewis, all of Long Beach.

Following the acquisition of the Carpenter Steel Co., Reading, Pa., by the Penn Seaboard Steel Corp., Philadelphia, Pa., operations have been increased from 35 to 40 per cent of capacity. The wage schedule of employees has been advanced, those earning 24 cents per hour and under receiving a 3- to 5-cent hourly increase, and proportionate advance to workers earning more.

THE CENTRAL IRON & STEEL CO., Harrisburg, Pa., is planning for the resumption of full operations at its mills in the near future. The plant is now running at close to 75 per cent of normal.

THE ALABAMA IRON & STEEL CO., Gadsden, Ala., is making repairs to the second furnace at its local plant, and is said to be planning to place the unit in blast in the near future.

THE ANDERSON-PRICHARD OIL CORP., Oklahoma City, Okla., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are L. H. and L. M. Prichard and J. Steve Anderson, all of Oklahoma City.

THE PRESTON CLAY CO., Canton, Ohio, has been incorporated with a capital of $2,000, nominal, to manufacture burned clay products. The incorporators are H. S. Preston and H. S. Williams, both of Canton.

THE STANDARD CASTINGS CO., South Bend, Ind., has been incorporated with a capital of $200,000, to manufacture iron, steel and other metal castings. The incorporators are John N. and Charles L. Zigler, and Richard A. Oglesby, all of South Bend.

THE BRICK & TILE CO., Egg Harbor City, N. J., has been incorporated with a capital of $100,000, to manufacture brick, tile and other burned clay products. The incorporators are C. A. Lunneman, John R. O'Neill and Alvin P. Risley, all of Egg Harbor City. The last noted represents the company.

MAX SEE & CO., INC., New York, N. Y., care of Littau & Seligson, 277 Broadway, representatives, has been incorporated with a capital of $10,000, to manufacture leather specialties. The incorporators are Max See and R. Mayer.

THE PRIMO PRODUCTS CO., Worcester, Mass., has been incorporated with a capital of $25,000, to manufacture paints, oils, etc. Irving S. Balcom is president and Henry K. Braetter, 73 Wellington Street, Worcester, treasurer.

Industrial Developments

OIL—The Catlin Shale-Oil Products Co., Elko, Nev., is developing a production of about 40,000 gal. of crude oil daily at its local refinery. A byproducts plant is operated for the recovery of gasoline, paraffine wax, lubricating oils, etc.

The Skelly Oil Co., Tulsa, Okla, is increasing production at its oil refineries to a point of about 11,000 bbl. daily. The gasoline plants of the company are running on a basis of about 25,000 gal. of gasoline daily, and this capacity will be advanced to 40,000 gal. at an early date.

IRON AND STEEL—The Illinois Steel Co., Gary, Ind., is now operating on a basis of about 85 per cent of capacity.

The Lebanon Iron Co., Duncannon, Pa., has reopened its local plant, following a suspension since 1920. Employment will be given to about 150 men, and this quota will be increased at an early date.

A total of 21 blast furnaces are now in operation in the Alabama iron districts, 8 of which are running on basic material and 13 on foundry pig. The different operating plants are: Tennessee Coal, Iron & Railroad Co., Birmingham, 8 furnaces; Sloss-Sheffield Steel & Iron Co., Birmingham, 5 furnaces; Woodward Iron Co., Woodward, 4 furnaces; Republic Steel Co., Birmingham, 2 furnaces; Alabama Iron & Steel Co., Gadsden, 1 furnace; and the Gulf States Steel Co., Alabama City, 1 furnace.

The Central Coal & Iron Co., Holt, Ala., is completing repairs to its local furnace and plans to place the unit in blast at an early date.

The Inland Steel Co., Indiana Harbar, Ind., is now operating at about 65 per cent of capacity.

The Central Iron & Steel Co., Harrisburg, Pa. is making additions to its working force and has advanced production in a number of departments.

The Bethlehem Steel Co. is said to be planning for the early resumption of full time production at its works at Steelton, Pa. The plant is now running on a basis of about 70 per cent of capacity.

The Ohio Falls Iron Co., New Albany, Ind., has placed its local plant on a double-shift basis of operation, giving employment to an increased number of men. The plant has been running full, on single shift schedule, for about 60 days past. The wages of laborers have been advanced 25 cents a day, making a rate of $2.50 a day.

Following a short shut-down for repairs, the Reading Iron Co., has resumed operations at its puddle mill at Danville, Pa. Wages have been increased at the plant, puddlers now receiving $7.50 a ton, instead of $6.50, as heretofore. The company is running full at its 9th St. mill at Reading, Pa.

The United States Steel Corp., Pittsburgh, is now operating on a basis of 75 per cent of capacity at its different mills, considered collectively.

The United States Cast Iron & Pipe Foundry Co. is running at maximum capacity at its plants at Burlington, N. J., and Scottsdale, Pa. Production will soon be advanced at the different plants units of the company in the south.

The Carnegie Steel Co. has resumed operations at the skelp mill at its Farrell, Pa., works, placing the plant on a full 10[illegible] per cent basis for the first time in about [illegible] years.

TIN PLATE—The Follansbee Brothers Co. Pittsburgh, Pa., has resumed operations at its tinplate mills at Follansbee, W. Va., and Toronto, O., giving employment to about 2,500 operatives, both plants.

METALS—The Golden Rod Mining & Smelting Co., Cardin, Okla., has resumed operations at its Mill No. 7, which has been closed down for about a year past. The plant will run on a schedule of 1,000 tons a day.

The New Cornelia Copper Co., Boston, Mass., operating properties in Arizona, is increasing production at its plant and expects to develop an output of about 4,000,000 lb. early in August, as against a production of about 1,500,000 lb. during recent weeks. Plans are under way for the construction of a new flotation mill at the properties, with capacity of about 5,000 tons.

MISCELLANEOUS—The Davison Chemical Co., Baltimore, Md., is increasing operations in its acid phosphate department at the local plant. The company reports a marked increase in orders for agricultural chemicals and expects advance production in this line at an early date. The factory is now operating on a basis of about two-thirds capacity.

The Barrett Mfg. Co. is arranging for the immediate resumption of operations at its paper mills at Kingston, Pa. A working force is being recruited.

The Dixie Consolidated Co., Birmingham, Ala., has placed its Pocohontas, Ala. graphite mill on a full capacity basis, giving employment to regular working force.

All cement mills in the Lehigh Valley section of Pennsylvania are now running at full capacity, with normal force of operatives. Continuous operation is planned for an indefinite period.

The McGraw Tire & Rubber Co., Easton, Palestine, Ohio, is advancing production at its local mill. A schedule of 2,300 casings and an equal number of tubes per day has been arranged. The plant is giving employment to about 600 operatives.

The Thomas Maddock's Sons Co., Trenton, N. J., manufacturer of sanitary ware, has developed production to maximum capacity, with regular working force, and expects to continue on this basis for an indefinite period.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold summer excursion meeting to Rochester, Montreal, Ottawa, Kingston, Toronto, Hamilton, Niagara Falls and Buffalo, Aug. 13-1[illegible]

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold annual convention and exhibition at Atlantic City, Oct. 23 to 28.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold 126th meeting at San Francisco, Calif., Sept. 25-29, 1922.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held in the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer, but will resume them in October.

THE SOCIETY OF INDUSTRIAL ENGINEERS will hold its next national convention and exhibitions of labor-saving equipment at the Hotel McAlpin, New York, Oct. 18, 19 and 20.

The Outlook For Coal

DEVELOPMENTS of the past week in the coal strike demand the attention of every coal-using industry. The complacence with which the strike was faced when it started was based upon two fortunate facts. First, there was a large stock in the hands of consumers; and second, the non-union mines could be depended upon to furnish nearly the normal summer consumption. As time has passed and JOHN LEWIS has specifically refused to yield to anything but a national settlement, the situation has grown more serious. Today the country is confronted with a real coal shortage coupled with a strong demand. The certainties now appear to be that there will be no wage reductions, that high prices will prevail for another year and that federal control probably will last throughout the winter. Of course, some settlement will be reached, but it is not known how long Mr. LEWIS can hold his miners in cash. Apparently he is the key to the situation, because he has persuaded union miners that the existence of their union is threatened and that a compromise will involve its destruction. He has imbued the strikers with this thought more strongly than any other leader has been able to do and consequently his ranks thus far are practically unbroken. No acceptable form of settlement is in sight at the present writing.

Statistically the situation is about as follows: The normal summer consumption has been 8,000,000 tons of bituminous coal per week; and up to July 1 the production of non-union coal was approximately 70 per cent of this figure, or about 6,000,000 tons. The effect of the rail strike, however, which apparently was directed with telling effect in non-union coal fields, has been so successful in curtailing production that last week it amounted to only 3,600,000 tons. Stocks in the hands of consumers on April 1 amounted to about 67,000,000 tons, with possibly 10,000,000 tons in transit. On July 1 the tonnage in the hands of consumers had dwindled to 2,000,000 and undoubtedly the tonnage in transit was greatly reduced as a result of the railroad strike. Thus we are faced with stocks that represent not much more than two weeks' supply, and a non-union production of less than one-half the normal consumption.

Obviously the situation called for federal control and for the consequent creation of a priority list. In fact priorities have been established not only for the supply of coal to industry but for the transportation of commodities as well. The transportation priority list gives preference in the following order: Food for human consumption, feed for live stock, live stock, perishable products, coal, coke and fuel oil. Coal will be furnished to industries according to the following priority list: railroads, ship bunkers, public utilities directly serving the public, electric power and light, gas, water and sewer works, ice plants, hospitals, government institutions, and lastly, "all other purposes," which includes iron and steel and allied industries. This suggests a possible advantage to those industries that buy power from a utility corporation.

Federal control has already shown an increase in the production and movement from non-union fields, amounting to about 20 per cent in the first week. Prices are stabilized and every effort will be made to prevent a runaway market. On the whole the situation is critical and will demand the most careful consideration on the part of consumers. Of the present non-union production of 4,000,000 tons about 3,250,000 tons will be allocated to utilities under the priority list, leaving less than one million tons per week for all other purposes. It is expected, of course, that this production will increase under federal control even if the strike continues. In the event of the resumption of mining in the unionized fields, it is probable that full production and distribution can be accomplished in 30 days. But even then it must be remembered that stocks have dwindled so low that there will still be the effect of a shortage long after full production is resumed.

The Value of Chemists' Clubs

WHEN the late Dr. MORRIS LOEB made the Chemists' Club of New York a living thing, he may have guessed—and again he may not—that many other chemists' clubs would spring into being, following the New York example. The fact was demonstrated that chemists are social beings and that, as in other agencies, there is great value in informal discussions. When chemistry was purely experimental in its nature, there appeared many reasons for workers in the field to keep what they knew to themselves and not to talk too much, lest some fact which the talker had observed might also be noted by somebody else before the former had profited by it in credit or in money. But now that chemistry, thanks to the introduction of physics into chemical thought, is becoming more and more of a deductive science, we—or at least a great many of us—need help and inspiration and jogging along in making our deductions. We need to talk things over, and the royal road for this purpose, to the man who is at once sympathetic and trustworthy, is by way of the club.

Our readers know of the Chemists Club at Chicago, we lately referred to the civic activities of that at Tacoma, Wash., and there are others in various parts of the country, some active and some inactive. Our present purpose, however, is to tell a little of the Chemical Industry Club of London, which is taking its place as a well-known feature of the professional life of chemists in England. Its quarters are in Whitehall Court, which is an institution of itself and is operated

by the same company that manages the Hotel Cecil. This Whitehall Court overlooks the Victoria Embankment and the Thames River, near the houses of Parliament and Westminster Abbey, and it provides sleeping rooms for the members and guests of a score or more of various clubs which it houses. Meals are served in the Chemical Industry Club rooms and in a common dining room, and one may, through his club facilities, also lodge his family in this very agreeable place. It is not available to the public, the charges are moderate, and the service excellent.

The club itself is small and has had the same trouble that the New York Chemists' Club had in the beginning of its career, in getting members to drop in and make themselves at home. But that phase is passing away, and now every table is often taken for luncheon, while at "the cocktail hour," from 5 to 7, one is sure to find a number of members.

The reciprocal arrangements between the Chemists' Club of New York and the Chemical Industry Club of London are a great convenience to the members of each. Membership in one is an introduction to and a warrant for the privileges in the other. None but an offensive and churlish person could miss the cordial welcome and good will that is thus extended to the American chemist in London, and we believe the same holds good of the English chemist in New York. At least, one hears abundant testimony to that effect. These things speak well of the chemical profession; indeed, we know of no other professional calling that provides this international reciprocity. It gives the chemist who has "arrived" far enough to be elected to membership the access to the eminent men in his own walk of life, both at home and abroad, and it adds charm to the profession.

A Rebuke To Insolence

PRESIDENT HARDING never was in better form than last week when he administered a well-merited rebuke to one J. CLEVE DEAN, who, signing himself as Chairman Railroad Employees' Publicity Association, addressed an insolent letter to the Executive. The Dean letter was filled with statements which the President rightly characterized as ungrateful and untruthful. Mr. DEAN indulged in silly sentimentalism when he stressed the strikers' loyalty and war service on European soil. He resorted to a cheap gesture in an effort to becloud the government's action when he warned against any "attempt to draft men into mining or railroad service." He made an idle threat when he predicted that under the government's "attempt to place American labor under the gun, nothing short of a revolution will happen." The President answered these vaporings "with that contempt which is felt by every good citizen in the hour of deep public concern."

There has been far too much loose talk on the part of labor leaders in the present strikes. Mr. DEBS was so incendiary in what practically amounted to a call to arms that most good citizens felt the government would do well to invite him to resume his residence in Atlanta. Mr. LEWIS has talked glibly of the government's use of troops as an "assembling and parading of engines of war to awe American citizens who are merely exercising their inherent constitutional right to cease work." Such words can be uttered only in insincerity and disloyalty.

Mr. GOMPERS has recently repudiated the Dean letter and has announced that there is no such individual. He expressed surprise that Mr. HARDING would answer the letter, but we believe that the country will be grateful to him for speaking as he did. Whether Mr. DEAN is a real or fictitious character, the sentiments expressed in his letter have characterized all too freely the utterances of other leaders who are not mythical characters. It is of no moment whether Mr. DEAN exists or not, but it is a source of gratification to a long-suffering and law-abiding citizenry to have the Chief Executive voice public sentiment in so decisive a manner.

Stabilizing Germany's Financial Affairs

GERMANY'S financial affairs are in such a hopeless tangle that we often catch ourselves bracing momentarily for a crash that seems inevitable. But for some reason or other it never comes. Not long ago when the news of Baron RATHENAU'S assassination caused the paper mark to tumble down to 18 cents a hundred, we thought the fall would surely prove fatal. But it didn't, even though it did represent a depreciation of considerably more than 99 per cent. Just where the endpoint lies we know not, but it seems certain that when the Germans themselves repudiate the mark an economic paralysis of all Europe is bound to follow.

It is no wonder then that the financial experts of England and France, in fact of the whole Reparations Commission, are giving serious concern to this problem. But even the layman can see that there are at least two things wrong with Germany's financial system that must be corrected. In the first place the printing press that has been inflating Germany's floating debt —sometimes at the rate of 10 billion marks a week— must certainly be stopped. And secondly, someone must put an end to the exporting outside of Germany borders of capital and every other movable thing of value. These are basic requisites for any lasting solution of Germany's troubles. The partial remission of the reparations debt and the floating of a German loan are important and essential, but these things take time and there are plenty of reasons to believe that they may come too late.

The proposal recently put forward by the Guarantee Committee of the Reparations Commission is basically sound in that it goes to the real sources of these difficulties. Under this plan two overseers from the Reparations Commission are to be accredited to Germany's Finance Ministry; one is to watch over income and the other over the outgo. These representatives of the Allies are to have access to all of Germany's finances. The floating debt, the budget, tax and customs receipts, imports, exports and all economic and financial dealings of the government are to be watched over by them. Here, however, is the inherent weakness of the plan, for the overseers must act in a purely advisory capacity. They are merely liaison officers between the Finance Ministry and the Reparations Commission and are not empowered to put into effect the reforms that the latter body may deem necessary. But, on the whole, this is a step in the right direction and the German Chancellor wisely sees in it a stabilizing influence that may help to bridge over the gap until a reasonable idemnity is definitely settled and reparations thus changed from a political controversy to an ordinary business debt.

In the meantime it seems that there is every chance

hat favorable developments will come from the meetngs of the French and British Premiers. France, vhich previously has been insisting on conditions that ave made an international loan impossible, has apparntly agreed that reparations shall be reduced from 32 to 50 billion gold marks providing Great Britain s willing to forgive the French debt. This tackling f the problem of interallied debts in relation to reparaions is admittedly a ticklish proposition, which was ut off at Genoa, The Hague and elsewhere largely ecause of America's attitude toward cancellation. The ecision to go ahead independently of the United States vould seem to be the first really constructive step that rance and England have taken in their own behalf.

We are not going to take sides on the cancellation uestion, for it is not an issue with which we are conerned—as yet. But it is our contention that every merican industry should be interested in stabilizing noney values in Europe and can well lend its support o any scheme that will make Germany a solvent urchaser of American goods and at the same time do way with the advantage which the greatly depreiated mark allows her in the world markets.

Wage Fixing By Numbers

DURING the school days of some of us, and at a relatively earlier time as regards others of us, here was published a book "Looking Backward" by EDWARD BELLAMY. The narrator was supposed to be n insomniac, who spent his nights hypnotized in an unlerground chamber, was lost track of when a great ire obliterated the approach to the chamber and was esuscitated long afterward when the United States ad become a socialistic state. It was a great book to ire the imagination of those who had little experience n ways of the world and traits of the human mind.

In this imagined socialistic state everyone had the ob for which he was fitted. The narrator was assigned he task of telling the people of the new generation ow men lived and behaved themselves at the time he ad got lost in his underground chamber. What tartled the new people most was the low price of votes. n the new time, votes had become so valuable, on ccount of the amount at stake, that men would not ell them, and the most intelligent and fairest minded nen got elected. One of the duties of the officials, f course, was to prescribe how much work each person ad to do in order to be given his fraction of the total roduction of commodities, etc.

We have had enough of developments of late to uggest how a socialistic state would work with men onstituted as they are. Some of the advocates of the ocialistic principle have urged that it could be applied radually to one thing after another. We find labor nions in existence, and the unions involving crafts that mploy large numbers of men are conspicuous for the igh wages they demand in proportion to the amount f work done. If in the socialistic state votes could ot be bought for a dollar or two apiece, as BELLAMY ntimated was the case in his time, would not the lasses of voters, by trades, that were in the largest umbers be most influential with the official who allotted he jobs? Is it not probable that if it required two nillion men to do a certain kind of work that craft vould receive the highest wages, the craft involving nly a million men somewhat lower wages, the craft counting up only a hundred thousand much lower wages, and the crafts having only a few members very low wages indeed? The actual difference might not be in wages. It might be in working rules, in hours of labor or in various other devices.

The condition observed today is a parallel to that of BELLAMY'S socialistic scheme. If there are only a thousand of a certain craft in the country, their going on strike makes little trouble. The trouble can probably do without their work for a while, or their places can be filled. If the craft requires a million men the strike soon affects the public, and it is difficult to fill so many places. In brief, it is a bad principle to live under, yet it looks very much as if we are expected to do so.

Does Your Roof Leak?

IT WAS RAINING and the shiftless tenant had just moved his chair a few feet so that the water from the leak in the roof would not drip on him.

"Why don't you fix that roof?" asked a stranger who happened to drop in.

"Well," drawled the tenant, "when it's raining you can't fix the roof, and when it's dry you don't need to fix it."

This remark is justly famous and perhaps we can draw from the story a legitimate parallel with conditions in chemical manufacturing. Not long ago at the convention of the National Fertilizer Association, its president admitted a lack of interest in research. He said that at the present time the industry can buy nitrogen either as nitrates or as sulphate of ammonia more cheaply than it costs to manufacture it synthetically. Therefore, it is not greatly exercised about research in synthetic ammonia or nitric acid. Interest was expressed in the work which the government was doing on phosphoric acid, but the fertilizer maker was not sufficiently excited about it, at least not to the point of spending any money on the problem. In other words, the fertilizer industry sits under a roof which needs patching badly and says: "What's the use of mending it, it isn't leaking now." The sequel to this may be that in five, ten or fifteen years when the fertilizer industry is buying synthetically produced nitric acid, ammonia and phosphoric acid at prices which the manufacturers of these commodities happen to demand they will have no cause for grievance on the subject. In fact it would not be at all surprising if manufacturers of synthetic nitric acid, ammonia and phosphoric acid would displace the present makers of fertilizers.

The fertilizer industry is not by any means the only offender, but it is a large and important one. Manufacturers of dyes in this country are beginning to lie back on their somewhat faded laurels. The minute they curtail research their roofs begin to leak, for dye making demands the most vigorous research of any industry.

It is the same old moral and we feel a little like the Scotch preacher who kept preaching the same sermon to his congregation. After the fifth or sixth repetition one of the elders of the church asked him why he didn't tell them something new, whereupon the wily pastor replied: "When you begin to live up to the message of this sermon, then I'll begin to think about a new message." So it is with chemical manufacturers. When the day comes, though we suppose it never will, when all chemical manufacturers understand and appreciate the vital nature of research work, then we shall stop harping on the old refrain. Meantime, is your roof leaking?

Kotaro Honda, Bessemer Medalist

AT THE annual May meeting of the British Iron and Steel Institute, the Bessemer Medal was awarded to Dr. Kotaro Honda, the Japanese scientist, in recognition of his researches into the magnetic properties of iron and steel.

Dr. Honda was born Feb. 23, 1870, and was graduated in the physics department of the Tokyo Imperial University at the age of 28. He remained in that institution for 10 years, doing post-graduate work and lecturing in physics. At the end of 5 years he received the degree of Doctor of Science. Much of his time was taken up in the study of magnetic phenomena, and several of his papers on magnetism appeared during the time he was at the Tokyo Imperial University.

The years 1908 to 1912 were passed studying in Berlin, Göttingen and Paris. In Berlin the magnetic susceptibilities of various chemical elements were studied in the private laboratory of the late Prof. H. du Bois. Dr. Honda's first work as a metallurgist occurred under Prof. Tammann's direction, in Göttingen, where he investigated the structure of metals and alloys.

In February, 1912, he returned to Japan, having been appointed professor of physics at the newly established Tohoku Imperial University at Sendai, a city of 100,000 inhabitants situated toward the northern end of the main island. The Iron and Steel Research Institute—of which more will be said later—was established in 1919 with Dr. Honda as president. Since that time his attention has been divided between the university and the Institute.

KOTARO HONDA, BESSEMER MEDALIST

The new Bessemer Medalist has an astonishingly fertile pen. Ever since his graduation he has been constantly investigating the problems of magnetism, both in theory and experiment. Forty-one scientific papers, written in English or German, contain the results of these studies. From a strictly utilitarian point of view his labors are more important for the development of a magnet steel of superior qualities. During his first 8 years after graduation Dr. Honda was also concerned with some geophysical problems, such as seiches (stationary undulations) in lakes and bays, geysers, and the periodic changes in level in deep wells —studies which resulted in nine papers written in English. Since his return to Japan in 1913, he has been chiefly concerned with problems in physical metallurgy of iron, steel and other alloys, and has written thirty-six papers recounting his findings, all of which have appeared, either as originals or reprints, in the *Science Reports* of the Tohoku Imperial University. Dr. Honda and his associates developed a method for studying changes in the magnetism of a metal as the temperature varies. Using this new tool, researches into the constitution of plain and alloy steels have been able to furnish a great amount of information on hitherto unsolved problems. Of these, perhaps the most notable are extended investigations into the constitution of chromium steels, tungsten steels and tungsten-chromium (high-speed) steels. Beyond all this, Dr. Honda has found time to publish several books in his native language: an 800-page Text Book on Physics for high school students; a similar but shorter volume for university students; a 320-page monograph on Magnetism and Matter; and three short brochures on certain investigations of iron and steel.

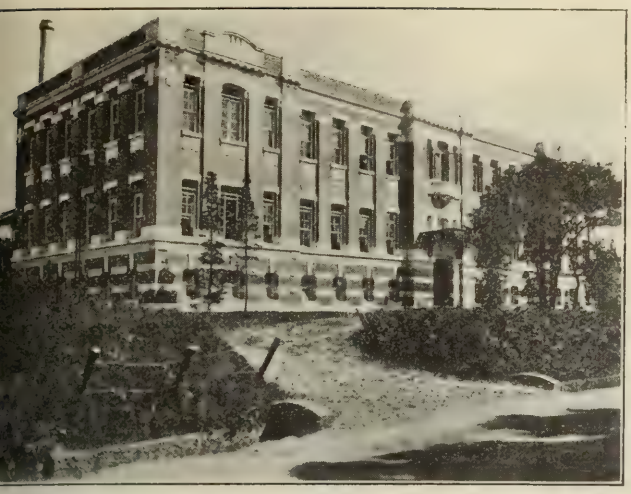
In addition to the Bessemer Gold Medal, Dr. Honda has received the Gold Medal of the Institute of Electrical Engineers of Japan, the Gold Medal of the Institute of Mechanical Engineers of Japan, and the Academy Prize of Japan, consisting of a medal and a grant of money. Dr. Honda, in addition to his duties at Sendai, is a member of the National Research Council of Japan and of the Aëronautical Research Institute of Tokyo.

Notes on the establishment and present scope of the Iron and Steel Research Institute may best be given in Dr. Honda's own words:

"The foregoer of the Institute, a temporary research institute for physics and chemistry, was started under my supervision in 1916 amid the great war with a personnel of six and an annual budget of 7,000 yen only, for the investigation of iron and steel. This budget was subscribed by Baron K. Sumitomo, of Osaka, Japan. Two years later, when research had been recognized by the public as very useful for the progress of science and industry, it was decided that the Institute should have a permanent organization.

Fortunately Baron Sumitomo again offered a donation of a building [shown in two views on the next page] and its equipment to the government; the latter agreed then to establish a permanent research institute for iron and steel belonging to the university. In 1919 the government organization was established with an annual budget of 50,000 yen and a staff consisting of the president, two research professors, five assistant professors, nine assistants and three mechanics.

"In 1921 an extension of the Institute was again undertaken by the government. It is to be completed



FRONT VIEW
IRON AND STEEL RESEARCH INSTITUTE

BACK VIEW
WITH SHOPS AT REAR OF INSTITUTE

n the three years from 1922 to 1924; the Institute is enceforth enabled to investigate not only iron and teel, but also non-ferrous metals and alloys. The ontingent outlay amounts to a total of 240,000 yen; he annual budget for 1922 is 90,000 yen, for 1923, 30,000 yen, and for 1924, 170,000 yen. After three ears, when the organization is completed, the staff will onsist of the president, four research professors, twelve assistant professors, twenty-seven assistants and twenty-five mechanics, etc.

"Though my institute is almost insignificant in its scale compared with a similar institute of metallurgy in your country, such as that in the Bureau of Standards, yet this is the only national research institute in our country—a miserable state from the scientific viewpoint."

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

THE annual meeting of the Society of Chemical Industry has already been described by Dr. Hendrick nd the chemical portion of what has this year been veritable American invasion has, if rumor is correct, ad every opportunity of comparing "dry" states with, or example, dry sulphate of ammonia as made in Scotand. A British contemporary draws attention to the pparent lack of a constructive and progressive policy n the part of the society. Although there has certainly een a "tendency toward routine and repetition" this harge cannot be laid at the door of the Chemical Engineering Group, whose sessions were an outstanding eature of the convention, and in more than one quarter t was suggested that this was a case of the tail wagging the dog. Experienced observers of British charcter, however, realize that new developments are often nitiated without warning and it is by no means improbable that the society may already have something p its sleeve.

SPENT OXIDE INCREASINGLY USED IN ACID WORKS

Many sulphuric acid plants had to burn sulphur instead of pyrites during the war period, but the partial eturn to more normal conditions of working has been elayed by the lack of demand for acid. Spent oxide as been accumulating at the gas works; partly because ome of them found the manufacture of anhydrous amonia more profitable than that of sulphate. These onditions have reacted upon each other to keep the rice of acid abnormally high and the revenue from he sales of spent oxide has been insufficient to offset ne purchases of acid. As a result there is a tendency to use spent oxide, sometimes enriched with sulphur, instead of arsenical cuprous pyrites, with all its attendant disadvantages and the subsidiary processes required for the manufacture of the superior grade of acid. The position will probably gradually adjust itself, but it is unlikely that the use of pyrites will again reach its former dimensions. Ammonia oxidation equipment for sulphuric acid manufacture continues to find favor, particularly in the larger works and for coke-oven installations; several firms are now able to supply standard equipment.

POLICY OF THE BRITISH DYESTUFFS CORPORATION

The annual meeting of the British Dyestuffs Corporation indorsed by a very substantial majority the policy of the directors and was a personal success for Sir William Alexander and his claim that the directing head of such an undertaking should be primarily an administrator with experience in administration of similar undertakings. Dr. J. G. Burnham, who will be remembered as the general works manager of the Gretna munitions factory, will act in a similar capacity to the corporation, and the research department will be continued as before under Professor Green and Mr. Baddiley. It is frankly realized that the corporation has a difficult task before it, but it is already evident that the very straightforward statement of the present position, the radical cutting down of expenses and inventories, and the improvement in quality of colors and in cash assets have restored a large measure of confidence in the future, particularly as personal issues have now been largely eliminated. Referring to the key industries act, it has been decided that boracic acid was wrongly included in the schedule and it will cease to be treated as a fine chemical and will be exempt from

duty. The hearing of a complaint that photographic hyposulphite of soda has been wrongly included in the schedule is of some importance because it is typical of a number of products which are regularly manufactured by the heavy chemical industry in a high state of purity, comparable with the purity of many fine chemicals. A prophet is never without honor save in his own country, but on the basis of recent decisions it is expected that the duty will be removed or a compromise reached.

Proposed Advisory Scientific Committee

Until it was realized that scientific advice was indispensable for the Munitions and War Departments, technical advisers were at a discount for political purposes. There is again a tendency to drop the scientific pilot, and it has brought forth in the form of a letter to the *Times* a concrete proposal from Sir William Pope to establish an advisory science committee to the Board of Trade. There is no doubt that this country has lagged behind other countries in the movement for establishing a system by which the government can consult not only the trades concerned but also more impartial experts before introducing half-baked legislation or regulations, and so avoid their inevitable reconsideration when subsequently criticized or actively opposed. It is felt, however, that liaison with science is essential not merely for the Board of Trade but also for other government departments, and that the continental system of registering scientific legal assessors and attaching them to the courts of law has much to recommend it. Something has already been done in connection with the administration of the dyestuffs and of the safeguarding of industries acts, but there is a dangerous tendency always to put the burden upon the same set of men, instead of spreading these responsibilities and diversions from normal activities to include some of the more active, if less experienced, specialists.

Industrial Devepopments and General Notes

Ransomes, Sims & Jefferies, of Ipswich, are now manufacturing the Kestner water tube boiler in this country and a brief reference may be appropriate as illustrating the way in which what might almost be termed a chemical engineering problem—hitherto an untrodden preserve of the chemical engineer proper—has been invaded by one of the world's leading chemical engineers. The Kestner boiler is the direct outcome of experience in connection with the evaporation and concentration of chemical liquors and resembles a standard evaporator except that the vertical tubes are arranged in the form of a double *W*, over which the flue gases take a zigzag path. To promote circulation, a number of the tubes are made of larger diameter and inside them are fitted smaller concentric tubes supported by spiders. In actual practice it is found that very little scaling takes place with normal waters, tubes can be replaced very easily and, the lower drum being freely suspended, all tubes are free to expand. An interesting feature is the possibility of combined gas and fuel firing, and it is understood that efficiencies of about 80 per cent have been obtained in practice with an evaporation of about 7 lb. of steam per sq.ft. of heating surface. The Kestner company in England has recently become the sole licensee in Europe of the Merrill process of industrial heating by oil circulation, originally developed in America.

Italian Chemical Industries

From Our Special Correspondent

Genoa, July 4, 1922.

THE month of June was full of upsets for the Italian chemical industries. The agitation among the workmen continued. But there was very little actual discontinuation of work and in the case of some soap, perfumery, shoe cream, match, beer, mineral water and superphosphates works, an agreement was reached with the workers that was followed on July 2 by a general contract of work in Liguria, Piedmont, Lombardy and Tuscany.

Petroleum Supplies

A new large firm has been formed for the development of petroleum in Italy and abroad. The Italian Government did its best to make arrangements with Russia, Poland and Rumania for facilitating the importation of petroleum from these countries, and three separate agreements were signed. The exploitation of the petroleum deposits available in Italy itself was also encouraged. The imports of this product during the last half of 1921 reached 64,636 tons, and those of gasoline 57,437 tons.

Caustic Soda

The Italian production of caustic soda continues good and it is gradually being extended. The products are more easily obtained on Italian markets than in the past and are nearly always offered at much lower prices than the imported products. This production is however, unfortunately still small in comparison with what would be required in Italian industry.

Tanning Materials

For assisting the leather industry, that is passing through a very severe crisis, the works producing tanning materials, and especially chestnut extract, kept their quotations low and their behavior was appreciated by the tanners that produced most of their leather through the use of this extract. The Italian producers of mimosa, oak bark and other extracts could increase their production by such procedure as well as making some exports. During the last half of the past year the exports of liquid tanning extracts reached 3,331 tons, and the exports of dry tanning extracts 613 tons; whereas imports of 219 tons of liquid extracts and 1,893 tons of dry extracts were noted.

Fertilizers

The demand for superphosphates, nitrate of soda and nitrate of ammonia was small, whereas a certain activity was noted with cyanamide, Thomas slag, sulphate of ammonia, chloride of potash and sulphate of potash. The imports during the last 6 months of 1921 were as follows: 18,625 tons of mineral and bone superphosphates, 4,075 tons of Thomas slag, 3,324 tons of nitrate of soda, 11 tons of calcium cyanamide, 609 tons of sulphate of ammonia, 3,662 tons of potassium fertilizers.

New Combination for Producing Tartaric Acid

The fusion of the firms Società Appula, of Bari, Società Italiana dei Derivati della Cellulosa, of Milan, and Società Anonima Acido Tartarico, also of Milan, has taken place, forming one large firm with a capital of 25,000,000 lire.

Handling the Finished Products of Industry—IV*

By Graham L. Montgomery

Handling in the Beverage Industry Consists of Handling Empty Bottles to the Filling Machines and Filled Bottles Away From These Machines —This Handling Is Essentially One Problem — Methods Used by the Beech-Nut Packing Co.[1] to Solve It

HANDLING equipment, in a beverage industry which bottles its own product, is an economic necessity. The cost of the labor required to perform this handling without the aid of automatic equipment is out of all proportion to the possible selling price of the beverage. As a result, all successful manufacturers of beverages use handling equipment in so far as they are able to make it fit in with other economic factors in their plants.

Reference to Article I of this series shows the handling equipment for finished products divided into three general classes: First, for handling bulk or unpacked products; second, for handling finished products packed in various kinds of containers; and third, automatic machines for handling the finished product through various processes such as packing, wrapping and filling.

Handling of Bulk Product

Handling of the first class, in soft drink manufacture, consists of handling by pipe line—using gravity head where possible and in other places using pumps. This is because the finished product is all liquid. The last actual process of the manufacture of a soft drink consists of mixing the flavored sirup and the charged water. This occurs exactly at the completion of the first class of handling, when these two finished ingredients are mixed in the bottles. Here we have an exception to the general rules laid down in the first paper of the series—for normally the manufacturing processes are all completed before any operation is encountered which can be justly classed as finished product handling.

Handling of the Second and Third Classes

In bottling a beverage, handling comprised in our second and third classes must be considered as one general process—from the handling standpoint. Here we find that the handling starts with the empty bottle and the empty case, and moves from this point in a continuous path through the operations of preparing the bottle for filling, filling the bottle, sealing, testing and labeling the bottle, packing the bottles in cases for shipment, and moving the filled cases to shipment or storage.

This succession of operations is essentially one problem, the crux being to feed the bottles to the filling head and to take them away from this machine in such a way that its maximum capacity shall be realized. In this paper we shall consider the handling problem of the beverage industry from this point of view.

Beverage Handling at the Beech-Nut Packing Co.

The manufacture of beverages at the plant of the Beech-Nut Packing Co. was described in *Chemical & Metallurgical Engineering* for July 26, 1922. In that paper a description was given of the operation of the automatic equipment as it affected the product. It will be shown here in what manner this automatic equipment ties in with the conveying equipment to make a continuous process of the bottling.

Bringing Empty Bottles and Cases Into the Plant

This plant owns its own box factory, in which the cases are made. Bottles are purchased on contract from various large bottle makers.

Both of these articles are brought to the plant in box cars. Fig. 1 shows several of these cars on the siding along the receiving platform. A car of empty cases is placed near the center of this platform, with a car of empty bottles on its right. A portable gravity roller conveyor is placed to lead from the car of cases to the stationary gravity roller conveyor, which leads along the platform. Another portable gravity roller conveyor is placed to lead from this stationary conveyor to the car of bottles. A third portable conveyor is placed to lead from the car of bottles to a point on the stationary conveyor further toward the right and lower down.

The car of cases is then unloaded onto the conveyor.

*Previous articles in this series have appeared in *Chem. & Met. Eng.* as follows: Article I, vol. 26, No. 18, p. 823, May 3, 1922; Article II, vol. 26, No. 19, p. 885, May 10, 1922; Article III, vol. 26, No. 24, p. 1,114, June 14, 1922.

[1]An article descriptive of the process used in the ginger ale plant of the Beech-Nut Packing Co. appeared in *Chem. & Met. Eng.*, vol. 27, No. 4, p. 150, July 26, 1922.

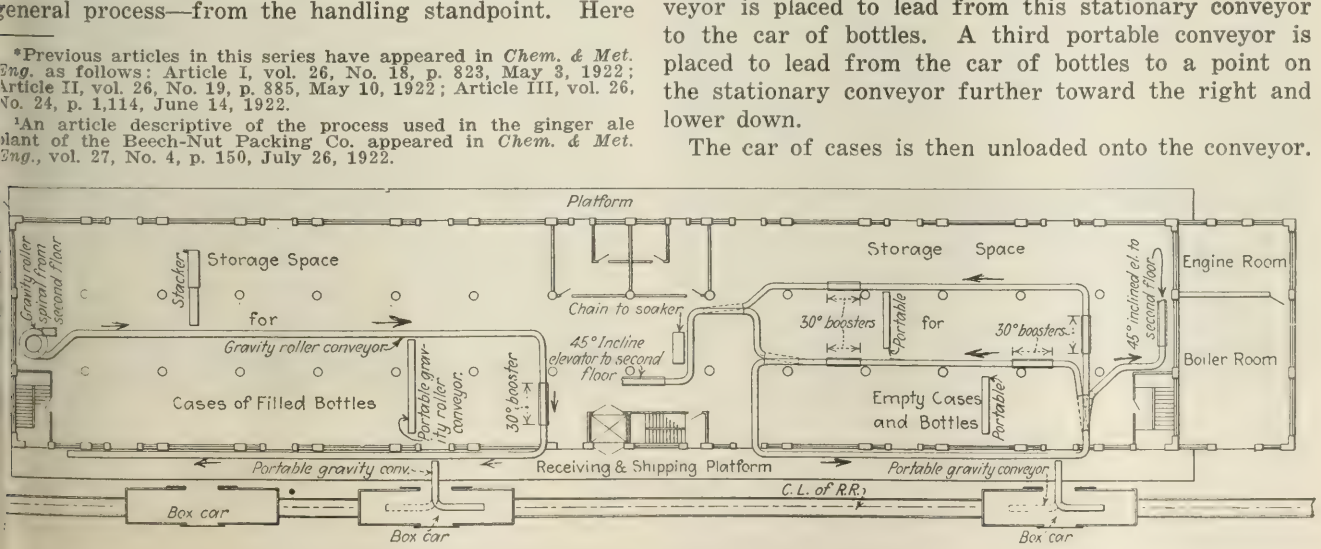


FIG. 1—CONVEYORS ON FIRST FLOOR OF PLANT

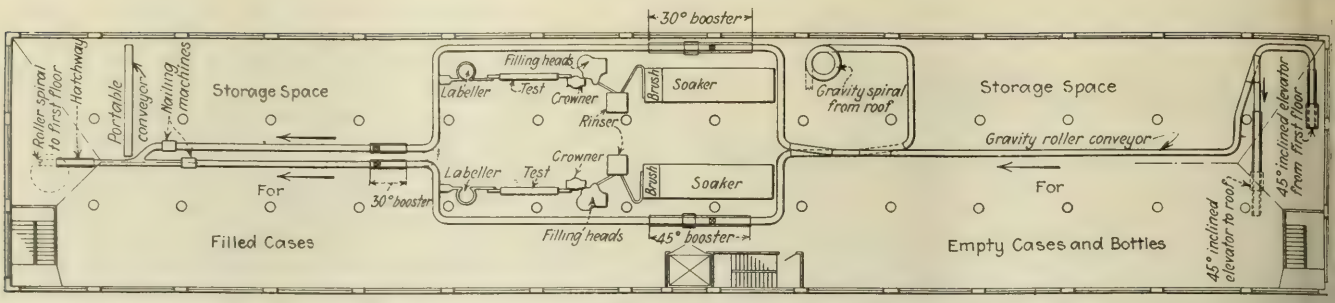

FIG. 2—CONVEYORS ON SECOND FLOOR OF PLANT

The conveyor takes the cases to the car of bottles. Here the workers fill each case with the empty bottles and place it on the third portable conveyor. This conveyor takes the cases back to the main gravity roller conveyor line and they are distributed from this line to the various storage areas for empty cases and bottles.

Storage System for Empty Cases and Bottles

By referring to Figs. 1 and 2 it will be noticed that the floor area at the right side of each drawing is marked "Storage for Empty Cases and Bottles." The space on the roof—shown in Fig. 3—is also used for this same purpose.

As the cases full of empty bottles pass into the building—at the right or east end as shown on the sketch in Fig. 1—they may be directed by means of the three-way switch to any of the storage areas mentioned above. The cases are stacked about 10 ft. high in these areas. It has been found inadvisable to use stacking machines to any great extent, as the same crew that would be used in connection with a stacking machine can stack these light cases more quickly by hand methods. The total floor area of these several storage spaces is about 18,000 sq.ft.

The gravity conveyors used in this system are at no point so high that the workers cannot easily remove a box. For this reason and due to the slope allowed in the conveyor for the purpose of causing the cases to move along it, it is necessary to provide power conveyors at intervals, as shown on the sketches, in order to boost the level back to a point where gravity can again be employed. These boosters, inclined at 30 deg. to the horizontal, are inclined package elevators of the push-bar type. They are made up of bars spaced at about two-case intervals and carried between two power-driven chains. The bed on which the cases slide is of steel slats parallel to the travel of the cases. Several of the photographs used to illustrate this paper show these boosters clearly. The elevators which take cases from one floor to another are of the same type, but are inclined 45 deg.

Conveying the Empty Bottles From Storage to Washing Machines

Before the bottles can be filled, it is necessary for them to be thoroughly cleansed.

Of course, if the required number of bottles and cases for one day's operation of the filling machinery were received each day, it would not be necessary to have any of this storage described above. But railroads do not deliver freight in this manner, and in order to guard against any possible shortage it is necessary to keep the storage area fairly well filled with cases and bottles.

The conveyor which distributes the cases to the storage areas on the roof—shown in Fig. 3—is continuous and also serves to take these cases out of storage. When it is desired to do this, the cases are placed on the conveyor and the conveyor leads them onto the roller spiral conveyor shown in the upper left corner of this sketch. This spiral conveyor, together with a short run of gravity at its lower end on the second floor, delivers the cases with their load of empty bottles to the second floor conveying system.

Out of Storage on the First and Second Floors

The bottles are carried through the soaker—which is the first element of the washing machinery—on conveyor. While the soakers are situated on the second floor, the conveyors that feed them loop down to the first floor, so that the bottles which are to be washed may be fed in on either floor. This serves the purpose of permitting the storage of bottles from cars into the storage spaces of the second floor and room at the same time that bottles are being taken from storage on the first floor to feed the soaker conveyor.

It will be noticed from the sketches and from the accompanying illustration that the gravity conveyors which handle the empty bottles have, in each case, on both the first and second floors a length passing directly in front of the soaker conveyor. The cases each with its load of empty bottles, are taken from storage and placed on a line of conveyor which leads either to the first or second floor soaker loading station; or, if used directly from the cars, they are routed over the central run of conveyor to the loading station on the first floor as shown in Fig. 1.

Handling Bottles Through the Washing Process

The conveying element of the soakers, as can be seen in the photograph, consists of two steel bar power driven chains, which carry the bottle holders spaced at regular intervals. The soaker tenders stand between the gravity conveyor and the front of the soaker. As the cases come along the gravity conveyor, they remove the bottles and place them in the compartments of the

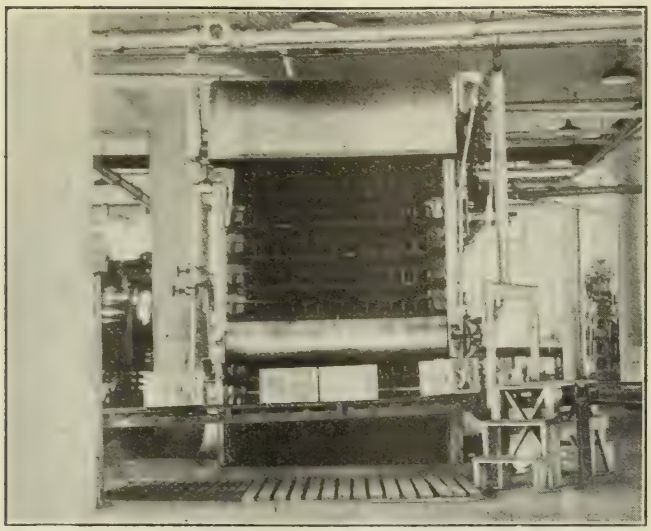
CENTER RIGHT—CASES AND EMPTY BOTTLES ON FIRST FLOOR CONVEYOR

LOWER RIGHT—SHIPPING CONVEYOR ON PLATFORM



GRAVITY CONVEYOR RUNNING IN FRONT OF SOAKER

bottle holders on the soaker conveyor. The empty cases continue along the gravity conveyors toward the west or left end of the building—passing around the washing, filling and other machinery—meeting the filled bottles at the point where these are to be loaded back into the cases. Reference to Fig. 2 will show clearly this routing.

After the bottles are placed in the soaker conveyor, the compartments in which they rest are automatically barred so that each bottle is held firmly and may be reversed without spilling from its compartment. The conveyor then carries the bottles up and down through each of three compartments filled with warm caustic solution and two compartments filled with warm sterilized water. This process—called soaking—requires 30 minutes for completion.

The conveyor, with its load of bottles, emerges from the soaker near the top and traveling straight downward. Part way on its downward path the bars are automatically removed from the bottle compartments and the bottles are discharged into the brushing machine.

Brushing and Rinsing the Bottles

As the bottles leave the soaker conveyor they slide, butt first, into the brushing machine. This machine—which is really one with the soaker—is of the same width and has a separate channel or path for each bottle delivered from the full width of the soaker conveyor—which is fifteen bottles wide. These channels slope sufficiently to cause the bottles to slide under the brushes. From that point they are moved forward mechanically, being rotated on their axes while passing under the brushes. These brushes rotate horizontally on axes at right angles to direction of bottle travel. These two motions serve to clean the outside surfaces of the bottles thoroughly, removing any old labels which adhere.

Passing beyond the brushes, the bottles are moved into an upright position and delivered to a single-chain conveyor traveling at right angles. This conveyor is made up as follows: The chain is a steel roller chain, carried on sprockets rotating in the vertical plane. The top strand runs between guides. The links of the chain carry steel plates in such a manner as to make a moving platform between these guides. On this moving platform the bottles are carried upright and in single file to the rinsing machine.

The rinsing machine takes the bottles automatically from the above-mentioned conveyor. In this machine while the bottles are in continuous forward motion, the inside of each is thoroughly brushed out and rinsed with sterilized water. This being completed, the rinsing machine delivers the bottles—upright and in single file—to a single-chain conveyor exactly similar to that described above.

Filling and Crowning the Bottles

This last conveyor moves the bottles a short distance to the filling machines. There are two of these, the "siruper," where the flavoring sirup is placed in the bottle, coming first and then the "filling-head," where the charged water is introduced and mixed with the sirup. The bottles move through these two machines in a continuous line.

After the filling operation is completed, the "filling-head" delivers the bottles to a third single-chain conveyor. This carries the bottles a short distance to the crowner, where the caps are crimped on. The bottles move continuously through this machine and are delivered to a collecting table.

Handling System for Test-Tank

The bottles are taken from this collecting table and placed by hand in wire baskets. These baskets are in turn placed on a slat conveyor about 6 ft. wide, which leads through the test-tank. This test-tank is about 15 ft. long, 6 ft. wide and somewhat over 2 ft. deep. The slat conveyor comes in over the top at one end, travels along the bottom of the tank and goes out over the top at the other end. In this way the baskets with their loads of filled bottles are submerged and the operator is enabled to detect and discard any that are imperfect. The speed of this conveyor is about 12 ft. every 10 minutes, so that the bottles are under water over 11 minutes.

As the baskets emerge from the tank, the bottles are removed by hand and placed on a single-chain conveyor. This conveyor is exactly similar to that described above and takes the bottles, erect and in single file, to the labeling machine.

This single-chain conveyor delivers its load direct

CONVEYOR FROM LABELING MACHINES TO NAILING MACHINES

the labeling machine. Here the desired labels are fixed and the bottles delivered to still another single-ain conveyor.

By referring to Fig. 2 it will be noticed that there a point—just beyond the labeling machine—where e single-chain conveyor widens into a collecting space. t this point are stationed workers, who take the ottles and place them in the cases waiting on the djoining roller conveyor. The roller conveyor is hori-ontal at this point, so that the cases collect and wait ntil needed. When a case is filled the worker, by a ight shove, sends it on down the conveyor, which has slope beyond this point.

Near the left or west end of each run of gravity onveyor shown in Fig. 2 a nailing machine will be oticed. As the cases come down the gravity to this achine, the nailing machine operator places the cover nd, with his machine, nails it down. At the same me the machine stamps the company's index number nd date on this cover.

To Storage or Shipment

Past the nailing machine, the conveyor delivers the ases to a roller spiral conveyor, which takes them a uniform and easy pace to the first floor. Here ey come onto another gravity roller conveyor. This onveyor, shown at the left or west end of Fig. 1, moves em past the storage spaces, where they may be stored tiers by means of a portable length of gravity con-eyor and a stacking machine; or they may be carried n out to the shipping platform, where a portable ravity conveyor takes them directly into the box cars. his main gravity conveyor is also utilized when cases re to be taken from filled-case storage to shipping atform.

Some Features of the Conveyors

The single-chain conveyors described above are a art of regular bottling equipment and are supplied by e makers of this equipment, as are such items as the onveying element of the soaker. The testing tanks nd conveyors were especially designed and constructed or the Beech-Nut Co. The remainder of the conveying quipment, comprising gravity roller conveyors, roller pirals, 30-deg. and 45-deg. incline package elevators, is lvey-Ferguson standard equipment supplied by the lvey-Ferguson Co. of Cincinnati, Ohio.

A study of the three sketches accompanying this aper in conjunction with the text makes it evident at this system is approximately continuous. It is lso automatic with the exception of the following rocesses: Unloading box cars, loading box cars, load-ng soakers, loading and unloading test-tank, and lacing filled bottles in cases. The only operations hich can hold up production are those included be-ween the soaker and the labeler. In order to guard gainst any delay at this point, this apparatus is in-talled in duplicate, each set having a capacity equal to that desired for the plant. The speed at which the ottles can be filled is the governing factor and the onveying, washing, crowning, testing and labeling quipment all has a greater capacity than the filling quipment, so that production can always be kept at a aximum.

Economic Side of the Installation

The Beech-Nut Co.'s plant here described has been in operation for the past 3 years only. Being thus one of the most modern plants of its type in this country, it was originally designed about as it exists at present. For this reason and because the beverage industry as a whole is near the same stage of development, it is impossible to give any figures which can serve as a guide to the economy of the automatic equipment. It seems, however, to be self-evident that the cost of handling the materials involved in a production of about 1,800 cases per day, such as we find at the Beech-Nut Co., would be absolutely prohibitive were manual handling used.

The installation here described is as near ideal for the purpose as any which could be found. The points of interruption in the flow, where hand transfer takes the place of mechanical movement, are as close to a minimum as the present available equipment will permit. Without doubt it will be possible at some future time to eliminate even more of these hand movements; but such improvement depends on new designs and inventions.

One of the economic features of this system worthy of notice is the small amount of power conveyor used —gravity supplying the motive power to the fullest possible extent. This may seem a small item; but the saving in expenditure over some bottling systems which depend on belts or apron conveyors should easily take care of the fixed charges on the conveyors.

The writer wishes to acknowledge the courtesy of the Beech-Nut Packing Co., of Canojoharie, N. Y., in opening its plant for the collection of the data of this article. The illustrations are supplied through the kindness of the Alvey-Ferguson Co., of Cincinnati, Ohio, manufacturer of the conveying equipment mentioned above.

Legal Notes

By Wellington Gustin

Contract for Use of Invention Valid Pending Application for Patent

An interesting point on an inventor's rights in his invention pending his application for patent is involved in the recent action brought by the Cook Pottery Co. vs. J. H. Parker & Son to recover royalties evidenced by promissory notes.

It appears that William Morrill Parker, one of the defendants, in January, 1915, filed application for letters patent in the U. S. Patent Office for the device known as the "Nailit knob" and thereafter it was controlled by the defendants; that in May, 1915, the plaintiff, learning of this device, entered into negotiations with defendants and procured a contract dated Oct. 8, 1915, for the use of this device in the manufacture of the "Wedge knob," then being manufactured by the plaintiff, on a royalty basis; that defendants further learned, after said contract had been made, that one A. H. Fargo had also applied for letters patent on a device similar to that of the "Nailit knob," and, in order to protect the plaintiff in the license granted it by defendants, acquired by writing under seal from Fargo, sole and exclusive license to use said invention, said sale and exclusive license being taken by J. H. Parker & Son, Inc., but that defendants J. H. Parker & Son should have the benefit of the same in order to

protect the plaintiff in the license granted to it by contract in October, 1915. It further appears that afterward, Feb. 3, 1920, letters patent for said invention were duly issued to an assignee of Fargo, who afterwards, on April 28, 1920, granted to J. H. Parker & Son, Inc., the exclusive right and license to make, use and sell devices embodying the invention, throughout the United States and its territories for the full life of the patent, and that defendants, by virtue thereof, and by the application by W. M. Parker for letters patent, have always controlled the right to manufacture and sell the "Nailit knob," a name used to designate any two-piece knob for electrical work assembled with a nail and fastened together by means of a washer or swedge or other projection on the lower part of the knob.

Plaintiff's Contention

Plaintiff contended that these facts showed that defendants, J. H. Parker & Son, did not have ownership and control of the "Nailit knob" device and that therefore they had no right to make the use of the "Nailit knob" device the basis or consideration of the contract of October, 1915, and that this contract was therefore without consideration, and void; in other words, that pending an application for letters patent, the applicant has no such ownership or control of the device sought to be patented as would give him the right to license or permit another to use it. It was claimed that plaintiff, or any other, already had full power and right to use this device in the manufacture of its "Wedge knob," pending defendants' application for patent thereon, and that, when it signed this contract, although under seal, there was no basis for its so doing—no consideration therefor. But on this point the Supreme Court of Appeals of West Virginia in this case at bar, 109 S. E. 744, laid down the principle that an inventor has an inchoate right of property in an invention pending his application for patent, with which he may deal as an article of property, citing Richardson versus Essex Machine Co., 207 Mass. 219. The court further says a license to use a device for which application for letters patent is pending may be given and if acted upon and the device used by the licensee in the manufacture of articles in which the invention is used, it will avail to protect the licensee in the use thereof after the invention is patented.

Question of Consideration

Now the doctrine is laid down by the United States Supreme Court that pending an application for a patent the applicant has no exclusive right to its use (Marsh vs. Nichols, 9 Sup. Ct. 168), and while this may be true, says the West Virginia Supreme Court, yet the use by another of the device sought to be patented, pending the application, ceases when the patent has been granted. It was pointed out that the inducement and consideration to the Cook Pottery Co. for the contract of October, 1915, was to obtain the right to use this device not only pending the application, but to be protected in its use after the device had been invented. The contract was given under seal and a sealed instrument implies a consideration has been passed.

Other observations in the suit were that where defendants were about to pass through bankruptcy when creditors would receive nothing, the saving of plaintiff's claim from the bankruptcy proceedings was a sufficient consideration for the continuance of an agreement between the parties; and again, when a contract under which one-half of commissions to be paid by plaintiff should be applied on debts owing from the defendan contained no definite agreement as to its terminatio it was not invalid for such reason, a reasonable tim being contemplated as a matter of law, and what woul be a reasonable time was for the court and jury t decide under the circumstances.

Reasonable Time for Delivery of Goods Imported With No Time Limit Set

A problem of purchase and sale of goods to be im ported is presented in the recent action of Garbiss Di sizian et al. against A. Klipstein & Co. to recover dan ages for breach of contract because the company refuse to accept a tender of shipment of 50 tons of gum arabi

Terms of Contract

The contract was dated April 23, 1918, and provide for the sale of 50 tons of 1918 crop, freight avera at 25c. per lb. net, c.i.f. New York. Shipment w "From Red Sea to New York on vessel Phyllis, whi is now on her way to Red Sea" and there was a provisi that "Sellers not responsible if shipment of merchandi or sailing of vessel prevented by any government reg lations in country of export or destination, by act God, perils of the sea, or by any other circumstanc beyond the seller's control."

On trial the defense was that there had been unreasonable length of time consumed before deliver giving the buyers the right to refuse to receive t goods.

Delay Not Unreasonable, as No Delivery Date Was Specified

The Phyllis was a sailing vessel. She began loadi in September, 1918, taking on 10,000 bags of gu arabic. Her cargo was loaded at Massowah. It car from vessels arriving from the Sudan, transferred her, after which she was towed 400 miles to Ade where she arrived in November, 1918. A mail-carryi vessel could not have reached the port of New Yo until December 31, 1918. The Phyllis landed in N York on May 29, 1919. She was a slow boat and h speed was not apparently in the minds of the parti at the time they made the contract. From these fa and circumstances the court found that there was unreasonable delay in making delivery of the gu arabic as required by the terms of the contract. T contract was in the course of performance. The sh was making her course to New York and in the abse of express terms as to time of delivery she had reasonable time under all the circumstances to ma the voyage. When the time is fixed, failure to ma delivery justifies a refusal to be bound by the contra Punctuality as to delivery was disregarded by the p ties in the agreement.

An attempt to rescind the contract or refuse to bound thereby, without warning or demand for t goods from the day of loading until their arrival New York, indicated a desire to find a convenient cuse for avoiding the consequences of the contract. drop in the market price of gum arabic in the meanti to 13c. per lb. may have been the reason therefor, sa the court.

Damages for the difference between the contract pr and the market price were demanded, together w storage, all totaling $12,965. The trial court found the sellers and this judgment was affirmed by the Uni States Circuit Court of Appeals, 273 Federal R. 473.

The Technology of the Carbon-Electrode Industry—III

A Critical Review of the Calcination Process: Why It Is Necessary and What It Accomplishes—Details in the Design and Operation of Electric and Gas-Fired Calciners, With Special Reference to Their Use in American Practice—Recent Developments*

By CHARLES L. MANTELL
Division of Industrial Chemical Engineering, Pratt Institute, Brooklyn

RECEDING articles in this series have dealt with the history of the development of the carbon-electrode industry and have discussed the raw aterials entering into the manufacturing processes. is the intention in the present installment to take up e first step in production—to discuss critically the lcination process and the equipment used therein. As eliminary to that discussion, it is perhaps desirable to rect attention to a number of terms more or less timately connected with the carbon industry. First, us consider the process of calcining itself. It is metimes defined as "the heating of a substance to a ite heat." This probably is in keeping with the iginal derivation from the Latin *calcinare*, meaning burn like lime." In the more restricted sense in ich the carbon-electrode industry uses the term, how-er, calcination refers to the heating of a carbonaceous bstance to the temperature required to yield a mate-l with a content of volatile matter not exceeding 0.5 r cent. Uncalcined materials are generally referred in the industry as "green," implying that further brication is required.

There may be said to be four reasons why calcination carbonaceous substances is necessary in electrode nufacture: (1) The green materials when ground not readily be bound together into an electrode of per density. (2) They are difficult to mold or rude. (3) They give off their volatile matter during king, thus resulting in a very porous electrode. (4) ey are poor conductors and have a much higher re-tivity than the calcined material. Calcination causes actual shrinkage in the volume of the carbonaceous bstance. It therefore effects an increase in the cific gravity or real density of the electrode as it is en termed in the industry.

Calcining Equipment and Its Operation

The calciners used in the electrode industry are either velopments of the industry and its close connection h electrothermic and electrolytic processes, or else adaptations from the manufacture of gas for indus-al or illuminating purposes. The electric calciners, "shrinkers," as they are often called, are example of first class, and the Woodall-Duckam and Glover-st vertical gas retorts are examples of the second. Of the two types of equipment used in the calcining cess—the electric and gas—the latter are by far the re prevalent. The electric calciners, however, were first to be used in the industry, and where electric ver is cheap and abundant they possess certain irable features. Each of the various types of calcining equipment is now to be discussed, with particular reference to those in American practice.

Intermittent Electric Calciners

Intermittent electric calciners usually consist simply of upright cylindrical steel shells lined with a highly refractive firebrick and resting on a ring of refractory brick work. A diagrammatic sectional elevation is shown in Fig. 2. Single-phase alternating current, with a voltage range of 30 to 60, is supplied to the aluminum or copper busbars encircling the shell.[15] Riser buses

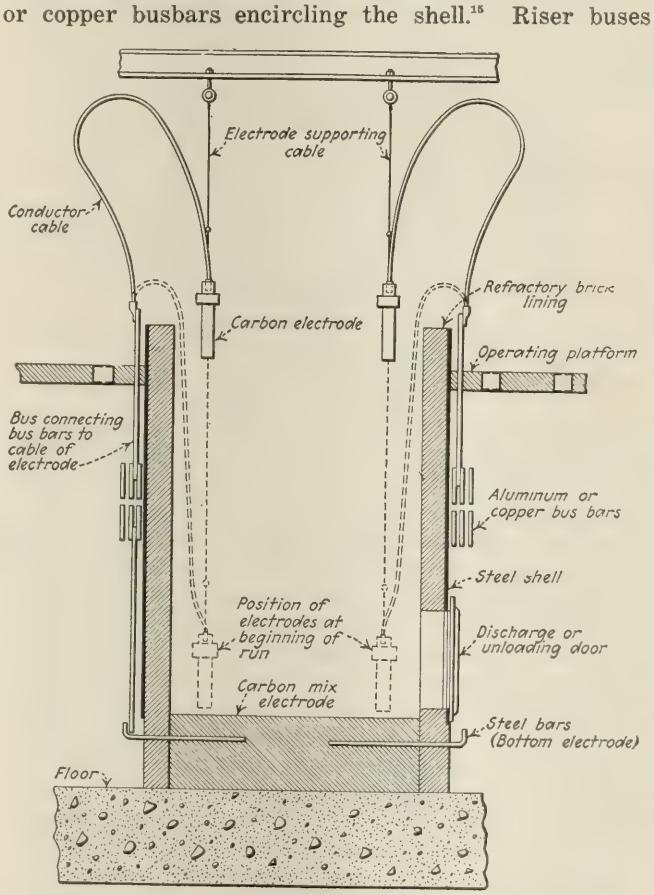


FIG. 2—SECTIONAL ELEVATION OF INTERMITTENT TYPE OF ELECTRIC CALCINER

from the upper ring of busbars serve to carry the current to the flexible conductor cables connected to the electrodes. The electrodes, usually 6 to 8 in. in diameter and 42 to 60 in. long, are suspended from above by the use of steel wire cables. Strain insulators serve to insulate the cast-iron head of the electrodes from the cable and the overhead supporting beams. These elec-

*Part I, which reviewed the history of the industry, appeared *Chem. & Met. Eng.*, vol. 27, No. 3, July 19, 1922. Part II, ing with the raw materials for electrode manufacture, ap-ed in *Chem. & Met. Eng.*, vol. 27, No. 4, July 26, 1922.

[15]For further electrical details than are given in this article, see Yardley, "Production of Shrunk Coke in Electrode Manufacture," *Chem. & Met. Eng.*, Feb. 15, 1922, vol. 26, p. 321.

trodes are protected from rapid oxidation by sheet-iron casings filled with a tar-bound mix of finely ground carbon. The construction is shown in Fig. 3.

The lower ring of busbars supply current to the bottom electrodes through risers which consist of rolled steel bars, bolted on the outside of the shell to the riser buses. The bars, usually 2 in. thick and 8 in. wide, are imbedded in a baked layer of a tar-bound carbon mix, which has been placed in the bottom of the shell while in a plastic condition and baked in place.

The arrangements and spacing of the suspended electrodes and the corresponding spacing of the bottom ones are as shown in Fig. 3.

In operating the calciner the top electrodes are

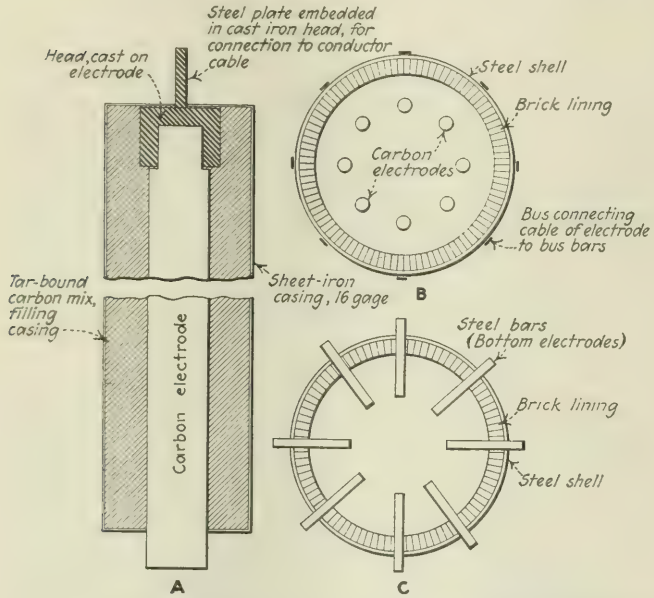

FIG. 3—CONSTRUCTIONAL DETAILS OF INTERMITTENT ELECTRIC CALCINER

A—Sectional elevation of electrode. *B*—Plan of top showing arrangement of electrodes. *C*—Plan of bottom showing arrangement of steel bars in bottom electrode.

lowered so that they almost touch the bottom and thus cause an arc to be formed. Green material, fed in at the top of the furnace, falls to the bottom and is heated by the arc. When the material is heated sufficiently to conduct the current, the electrodes are gradually raised, the arc broken and heating continued through the electrical resistance of the charge. More and more material is fed in at intervals and the electrodes raised as each additional layer of the charge becomes conductive. In this manner the electrodes are gradually raised from the bottom to the top of the calciner during the course of 8 to 12 hours. Heating is then continued, usually for an additional 12 hours. After about 24 hours the top electrodes are raised out of the bed of heated material and the charge is permitted to stand or "soak" for 24 hours before it is unloaded. This is done so that the charge will develop the same heat in all portions of the material, and time will be allowed for the volatile matter to escape through the charge. Furthermore, it is necessary for the whole mass to cool somewhat before unloading. It has been found that the percentage of volatile matter of the calcined coke varies inversely with the "soaking" time; the longer the soaking time the lower the volatile matter.

The charge is unloaded from the calciner by opening the discharge door on the side, breaking down the brick work, and hauling out the coke with long-handled rakes. As the material is still red hot, it is usually cooled by spreading it out on the floor in thin layers, or when necessary, sprinkling it with a fine spray of water. Wetting must be very carefully done, however, in order to avoid an excess that will not be evaporated by the coke. Moisture specifications for calcined coke call for a maximum of 0.3 per cent of water in order that when the material is finely ground it will not clog or "plug" the grinding mills.

The Trend of Recent Developments

The development of electric calcining units, particularly during the last 10 years, might well be shown by a brief review of the patents on the subject during that period. The developments have been along the lines of continuous furnaces, with attention given to the preheating of charges and recovery of the sensible heat of the calcined material as well as to the recovery of the valuable combustible gases produced as a result of calcination.

Attempts have been made at various times to convert the intermittent vertical type of furnace into a continuous one by providing it with some means of removing the calcined coke as it has been calcined. In most of these experiments there was little, if any, cooling of the coke and no sensible heat recovery; furthermore, the gas produced in the process was lost. These studies have resulted in only slight improvements over the original intermittent type of calciner.

Brown[16] is responsible for the adaptation of the hollow electrode to electric calciners. One of his earlier furnaces is shown diagrammatically in Fig. 4. It consists essentially of a hollow electrode located a

[16]John W. Brown, U. S. Pat. 1,067,795 (July 22, 1913).

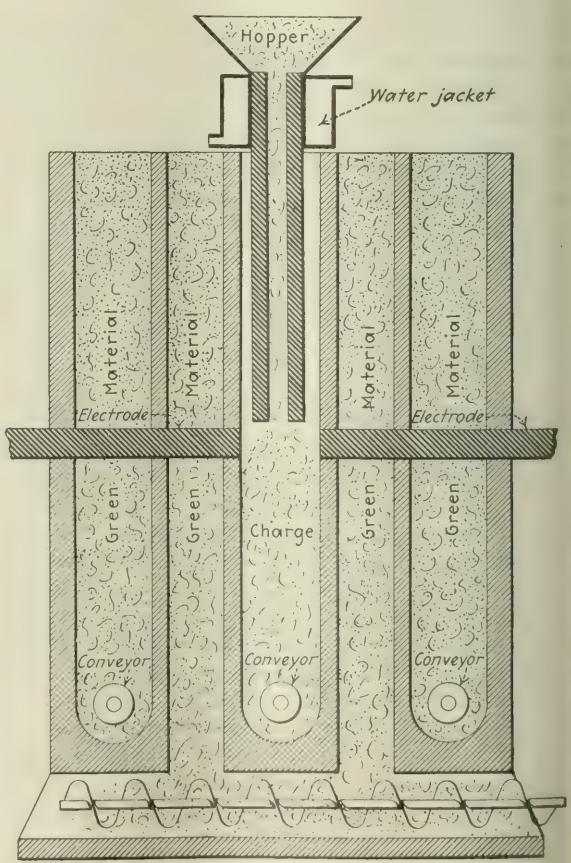

FIG. 4—HOLLOW ELECTRODE CALCINER (EARLY DESIGN)

e top of the furnace and passing through the cover, rough which the material to be calcined is fed. There e two solid electrodes set horizontally through the le walls of the furnace. The radiated heat of the arge undergoing calcination is made use of by caus- g green material to pass on the outside of the mate- al part between the inner and outer shells of the rnace before being placed in the heating zone. The ethod will be easily understood by referring to the ure. Some sort of conveying machinery serves to move the heated coke from the various chambers.

Brown next expanded the idea of using a high tem- rature and exposing the material to this temperature r only a short time by making the passage through e furnace very rapid. Fig. 5 shows an extension of s method of heat recovery by the use of surrounding yers of uncalcined material passing in the same direc- on as the charge.

In 1915 Brown[17] patented an electric calciner which

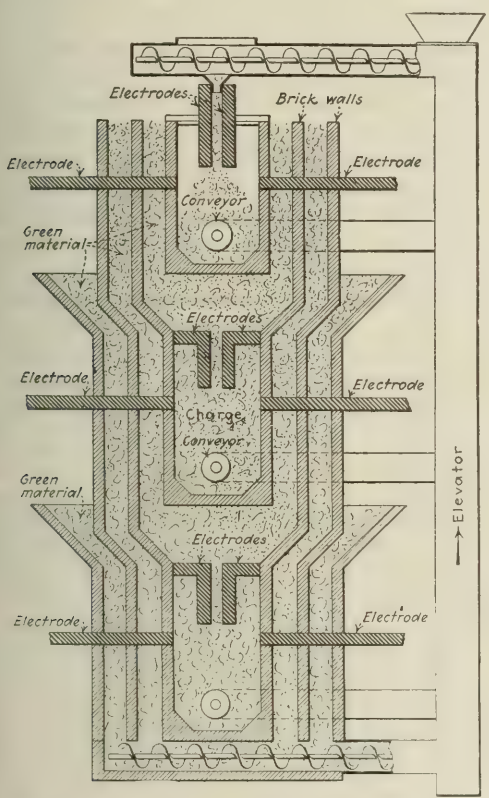

FIG. 5—COMBINATION OF HOLLOW ELECTRODE CALCINERS TO UTILIZE HIGH TEMPERATURE AND SHORTER TIME OF EXPOSURE

is continuous in its operation and recovered the seous products of calcination by a suction system. his is shown in Fig. 6. The charge enters the furnace om the hoppers at the top, dropping down through e opening between the upper electrodes. It is cal- ned during its passage between the upper and lower ctrodes. The lower electrodes are hollow and serve a means of entrance for blowing in gases drawn off other portions of the furnace. These gases cool the ctrodes and in their upward passage after being ated in the heating zone serve to preheat the cool un- lcined coke. The walls inclosing the charge are of rbon, and are insulated from the outer retaining lls by some good non-conductor. The gases resulting from calcination are drawn upward and are cooled in the the condensing chambers C_1, C_2, C_3, C_4, C_5, from which they are drawn through pipes to the exhaust fan. The calcined coke is removed at the bottom of the chamber by a conveying apparatus.

Later a furnace[18] was brought forward which was continuous in operation, recovered the gases resulting from calcination and used these gases to reclaim heat

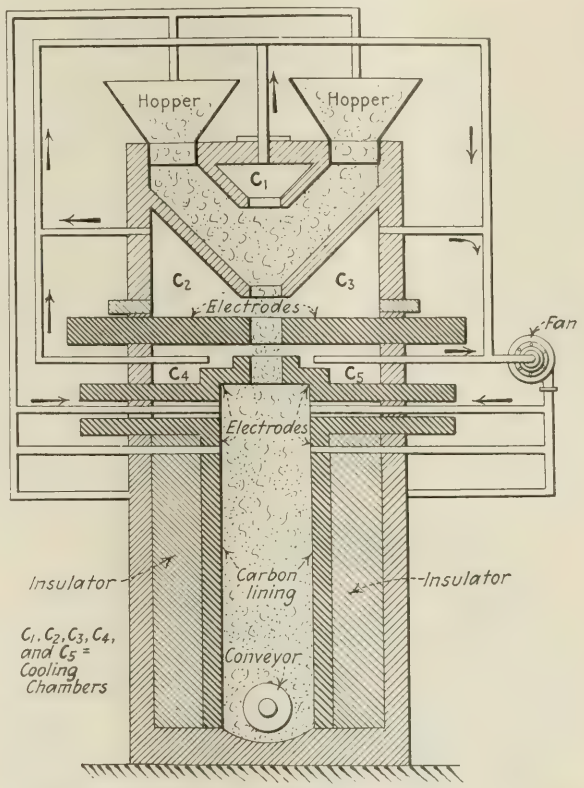

FIG. 6—AN EARLY DESIGN OF A CONTINUOUS CALCINER

from the calcined coke and preheat the green charge. A diagrammatic sketch of the furnace is shown in Fig. 7. Essentially the unit consists of a brick shell in which there is an upper and lower electrode. The charge enters through an opening at the top and passes by the upper electrode into an inverted conical shaped chamber which is carbon lined, then into a restricted cylindrically shaped chamber, also carbon lined, where most of the calcining takes place. Dropping from here into another carbon-lined chamber shaped like the frustum of a cone, the charge finally passes to a conveyor mechanism which removes the material from the furnace. Calcining takes place as current is introduced into the furnace through the upper electrode. Some of the current will pass through the adjacent charge and some through the chamber lining to the cylindrically shaped portion of the furnace, where, due to the negative coefficient of temperature resistance of the carbonaceous charge and the construction of the side wall lining, most of the current passes through the charge. The side wall lining is built of carbon blocks with surfaces corrugated where they come in contact; as a result their contact resistances are very high (see Fig. 7). From then on most of the current passes to the side walls and to the lower electrode and only a small portion through the charge to the electrode. The calcined material is cooled

[17]U. S. Pat. 1,143,940.

[18]U. S. Pat. 1,147,703.

by coming in contact with gases blown in through the bottom of the furnace. The gases in their upward passage cool the heated material, but are themselves heated at the heating zone. The heat they absorb at this point is transferred to the cold green material through which the gases rise, thus preheating it.

At various times patents[19] have been granted for furnaces in which portions of the charge were burned in order to preheat the materials before calcination and also to lower the cost of the process by reducing the amount of electric power consumed.

Probably the most recent patent on the subject is one for a ring-electrode, continuous-type calciner.[20] This type provides for continuous operation, recovery of the sensible heat of the calcined material, recovery of the gaseous products of the process and preheating of the uncalcined material. A diagrammatic drawing is shown in Fig. 8.

The furnace is of the vertical type, made up of three flanged sections. These sections are insulated from one another and the upper and lower ones lined with carbon electrodes or other carbon material. The middle section is provided with an insulating refractory brick lining. The heated portions of the shell are jacketed for water cooling. Material to be calcined is fed into the furnace continuously through the top. Gases arising from the

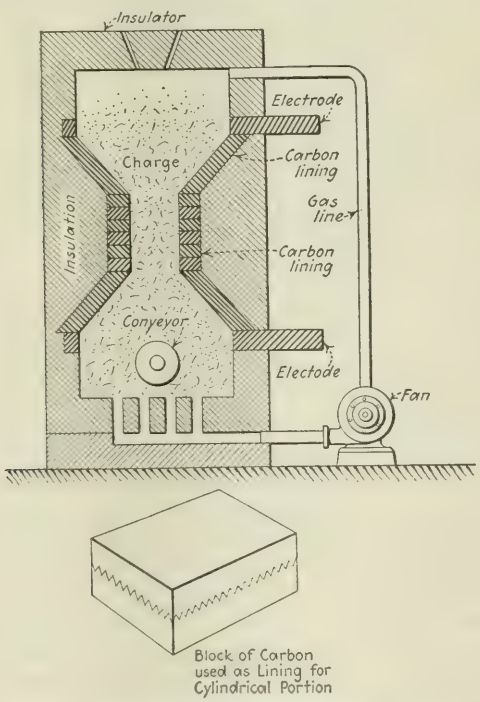

FIG. 7—ANOTHER EXPERIMENTAL DEVELOPMENT OF ELECTRIC CALCINER

expulsion of volatile matter pass off through an offtake at the top. A tee in the pipe allows some of the gases to be returned to the furnace at the bottom after the gases have been scrubbed, cleaned and cooled. The cold gases in passing up through the calciner cool the descending coke, pass through the heating zone between the upper and lower electrodes and cause a more even distribution of the heat. In passing off at the top, since the gases are now very hot, they heat the descending cold green materials and cause them to become conductive by the time they reach the zone of electric heating. Coke is extracted mechanically at the bottom.

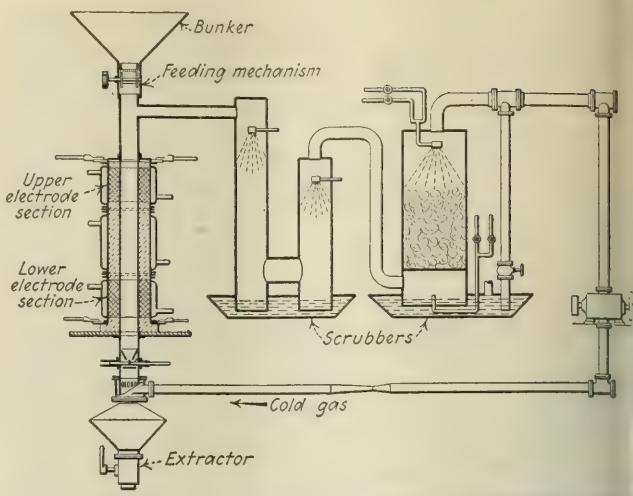

FIG. 8—SECTIONAL ELEVATION OF A PATENTED RING ELECTRODE TYPE OF ELECTRIC CALCINER

Practically all of the types of electric calciners mentioned use single-phase alternating current. In the movable electrode type care must be taken that all of the electrodes carry nearly the same amount of the current, otherwise one portion of the charge will be overheated and another not heated enough. The electrical load on the different electrodes is kept the same by the use of small control board lights. These are low-voltage lamps connected individually to current transformers placed around the riser buses. Evenness of load on the different electrodes is indicated by all the lamps glowing with the same intensity. Due to the negative temperature coefficient of resistance of carbonaceous materials, the tendency during calcination is for the current to follow the path first established. With increased heating, there will be decreased resistance and one portion will absorb most of the current.

Woodall-Duckam Vertical Retort System

The use of Woodall-Duckam retort for calcining carbonaceous materials is an adaptation from the gas industry for which it was originally designed. It was first introduced in England in 1903 and in this country not long afterward. The principle of the system may be more readily understood from Fig. 9.[21] Coke or coal is fed through a hopper at the top of a vertical retort heated on the sides. The speed of descent is so regulated that the coke is gradually calcined in its passage through the retort. The material is heated as it descends, and the gases from the volatile matter are evolved as the material reaches the proper temperature zones. The gases ascend, and are taken from the top of the retort. Thus the process is really one of fractional distillation.

The amount of material fed to the retort and the rate at which the charge descends are automatically governed by the rate the coke is removed from the bottom of the retort.

The retorts are rectangular and tapered from top to the bottom. The retorts walls are formed of tongue-and-groove bricks, paneled out at the back so that the heat is readily conducted to the charge. The heating flues are vertical, the division walls of the bricks being bonded into the walls of the retorts and also into the back walls of the flues.

The gas from the producer (either built in or an o-

[21]The author is indebted to J. S. DeHart, Jr., of the Is... Porter Co., of Newark, for the use of cuts illustrating the Wood... Duckam system.

de one) or else calciner gas om the operation of the re- rt, and the secondary air om the recuperator are ad- itted at the top of the verti- l flues and burn downward. he secondary air passes ound the lower end of the etort before it enters the re- perator. As now built, this ecuperator is of box con- ruction for the waste gas ith the air baffling on the utside. The temperature of he secondary air is raised al- ost to that of the waste ases. Dampers are provided t the bottom of the retorts o that the pull can be reg- lated to both sides of each etort. Main dampers are rovided on the waste gas utlet of the recuperator. egulating dampers are pro- ided on the gas and second- ry air flues to each pair of etorts.

In shrinking petroleum oke in these retorts, tem- eratures of 1,050 to 1,250 eg. C. are maintained, re- ulting in waste gases in the ecuperators with tempera- ures of 650 to 850 deg. C.

In the Woodall-Duckam ex- ractor the coke is cooled by he water jacket before it is ischarged. Fig. 10 shows he sectional elevation of a ypical plant for the calcina- ion of petroleum coke such s is built by the Isbell- 'orter Co. of Newark, N. J., vhich holds the Woodall-)uckam rights in this coun- ry. The plants are built ither with or without an in- ernal gas producer. When etroleum coke is used much ghter gas is given off than ith coal so that the brick- ned gas main may be sub- tituted for the more compli- ated hydraulic main gener- lly used in the calcination f coal.

The temperature of the ombustion chambers is ighest at the top where the eat is most readily absorbed y the cold material, and west at the bottom where the charge is completely lcined.

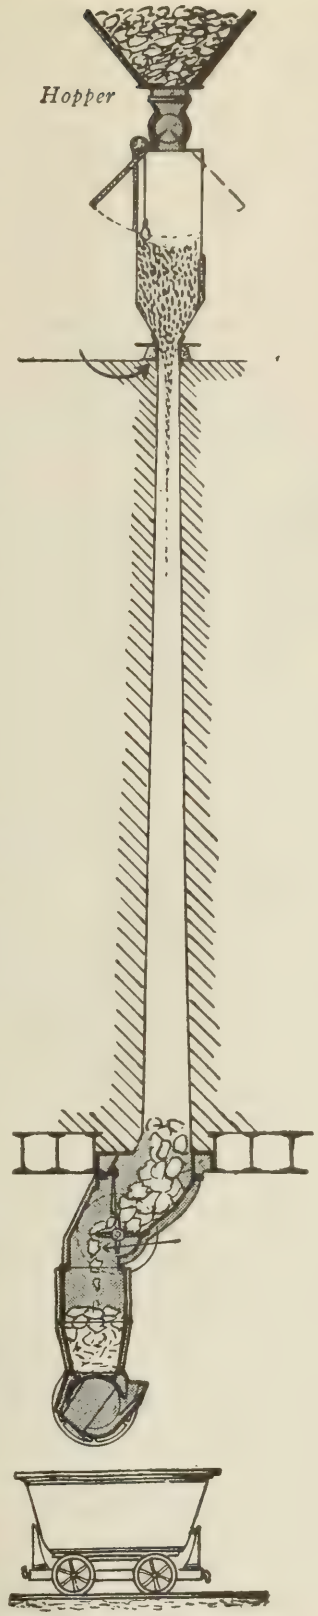

FIG. 9—SCHEME OF WOODALL-DUCKAM SYSTEM

Glover-West Vertical Retort System

The Glover-West system of vertical retorts was based n patents granted in 1905 to Young and Glover. In sic constructional details these retorts resemble those used on Scottish oil shales. In 1909 the present Glover-West system was introduced into England. As in the Woodall-Duckam system the calcination is continuous, but the methods of arranging for this vary in some detail. In the first place, the retorts are oval in section, instead of rectangular, and are built up of concentric fireclay rings. The bottom 3 ft. of each is composed of cast iron or special silica blocks and forms a regeneration chamber for the secondary air entering the producer. The passage of the gas from the retorts may be followed by means of Fig. 11. An outlet is provided at the base of each coal-feeding hopper, whence the gas is conducted by a 7-in. pipe to a dry main. Each outlet pipe is fitted with a valve which is brought into use when a retort is out of action for scurfing purposes.

The coke extraction is continuous and governs the rate at which coal is delivered. The extractor consists of a slowly revolving vertical worm, driven at a speed of one revolution in about 35 to 40 minutes. The extractor is built in two halves so that one half may be removed and the retort readily inspected. The speed of the extractors is adjustable. Dropping from the

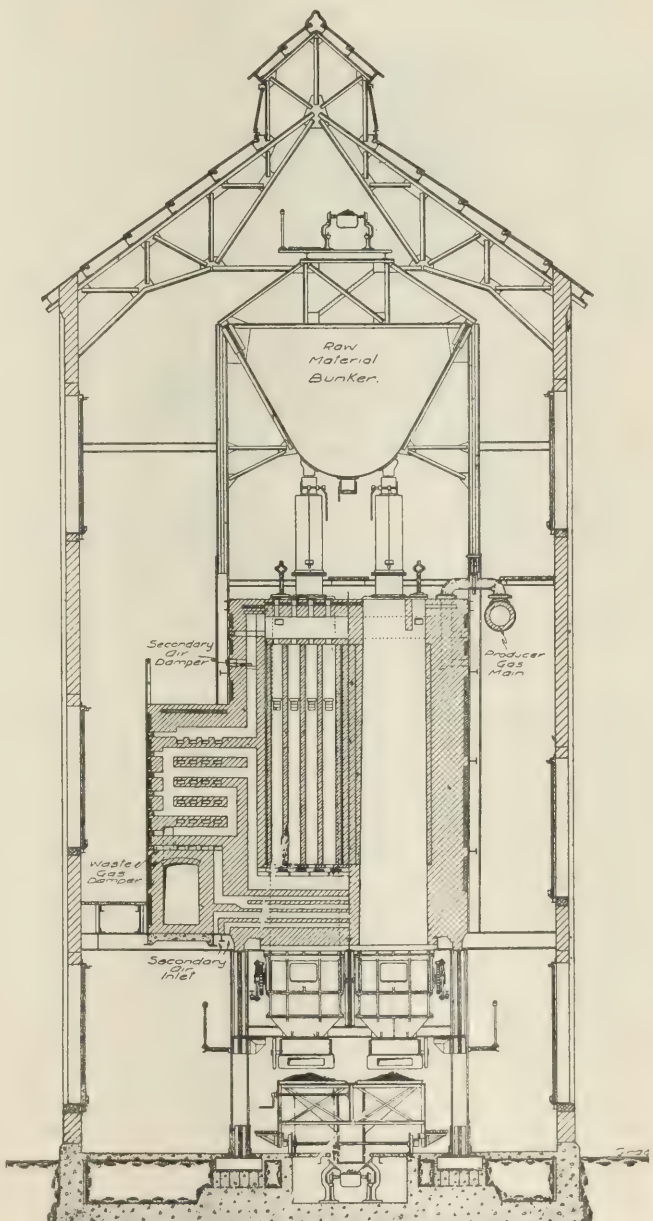

FIG. 10—SECTIONAL ELEVATION OF TYPICAL INSTALLATION FOR REDUCTION OF CARBONACEOUS MATERIAL

extractor, the coke passes into a chamber fitted with a self-sealing lid and is removed from this at intervals of about 2 hours. The system of heating the retorts differs from that of the Woodall-Duckam in that combustion takes place toward the bottom of the retorts and the waste gases pass around the upper portions into the horizontal circulating chambers before finding their way to the chimney. On account of the cooling action of the secondary air passing around the base of the retort, no water quenching is needed and the coke is discharged from the lower chambers practically cold.

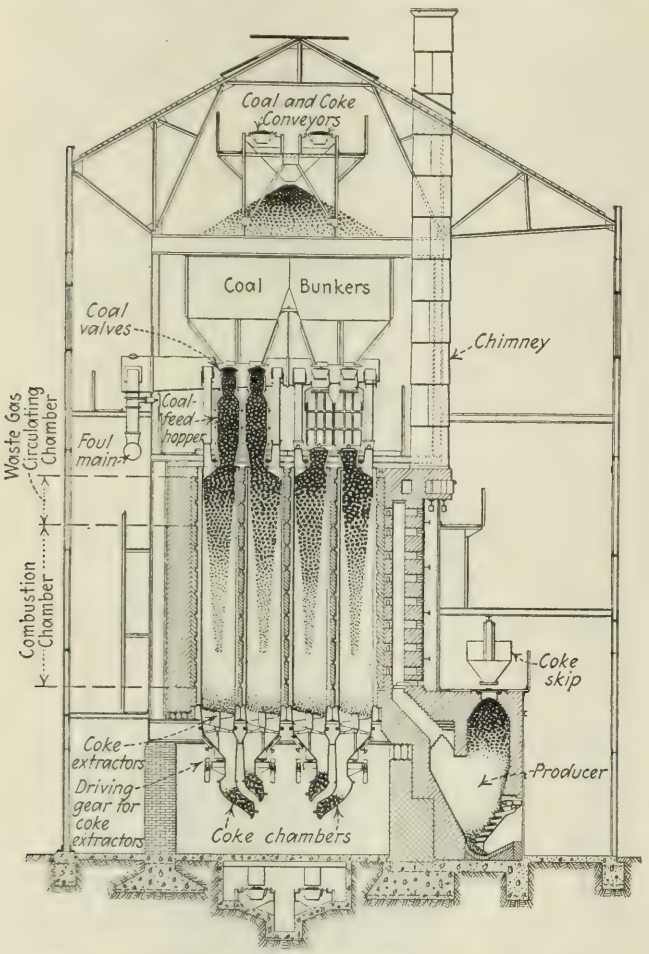

FIG. 11—SECTIONAL ELEVATION OF GLOVER-WEST VERTICAL RETORT SYSTEM

The retorts are heated in a series of superimposed chambers and the heats can be varied at will. The chambers are divided into three portions—the top or waste gas circulating chambers, the middle or heating chambers, and the bottom or regenerator chambers.

The calcined carbonaceous material is tested for volatile matter content by the standard method. The specification for volatile matter limits it to a maximum of 0.5 per cent. Moisture determinations are also made, for the specification allows only 0.3 per cent moisture. Resistivity is determined on ground samples (screened between 35 and 100 mesh), by measuring the drop in voltage at a constant amperage through a definite volume of the material. From this the resistivity is calculated. Usual specifications call for a maximum of 0.05 ohm per inch cube.

Conclusion

In general, due mostly to the high temperatures reached in electric calcining than in gas-fired calciners, a denser coke or calcined product will be produced in the electric calciners. The advantage of gas-fired units lies in their lower operating costs, aided by the fact that they can use the gases driven off in calcining to heat the retorts, so that there will be practically no power cost. In electric calciners there is a tendency to graphitize partly some of the charge and in this manner produce a calcined product of lower resistivity than would be possible with gas retorts.

The basis of the finished electrode may be said to lie in the proper calcination of materials. Without it the arts of the expert carbon maker are of no avail.

Editor's Note—It is the author's intention in the next article to discuss the grinding, mixing, molding and extrusion processes in the electrode industry. This will appear in a subsequent issue.

British National Physical Laboratory Report, 1921*

Work in the laboratory on iron and steel has been devoted mainly to the further investigtion of the constitution of the iron-nickel-carbon alloys, the iron-phosphorus alloys, and to the determination of the temperature of melting in the iron-carbon system. For this latter purpose an electrical method, first developed in connection with the study of the constitution of the aluminum-copper-nickel system, is being successfully applied.

A considerable amount of investigatory test work has been carried out in relation to cases of failure in iron and steel, particularly, the cracking of boiler plates around rivet holes.

The main work to be undertaken under the auspices of the alloys research committee of the Institution of Mechanical Engineers will relate to the study of ferrous alloys, primarily binary alloys of iron with other elements in the absence of carbon. This work will include in the first place the determination of the constitutional diagrams of some of the more interesting systems of this kind, and where possible the correlation of the diagrams obtained with the physical properties of the materials.

Research will be continued upon the physical structure of metals and alloys, particular attention being given to the measurement of the heat generated by plastic deformation. The experiments already made on the behavior of the more plastic metals in tension will be continued and efforts made to obtain a higher degree of accuracy in the determination of the heat evolved. Incidental to the above researches, the further investigation of the properties of amorphous metal is required.

As is well known, the Brinell hardness test is unsuitable for steel whose hardness number exceeds 500, on account of the permanent deformation of the ball which takes place in such cases. Some consideration has been given to the possibility of determining a scale of hardnesses for very hard materials from the amount of permanent flattening of the ball, and an instrument has been constructed in the workshops by means of which this flattening can be measured. Given careful manipulation of the instrument and a trained observer and provided that a supply of steel balls of uniform hardness can be obtained, it is believed that the method will be a valuable one in discriminating between the hardness numbers of very hard steels.

Boiler Plate After Cold-Work or Work at Blue-Heat

High Proportional Limit Exists While Tempering Cold-Rolled Plate at 300 Deg. C., or After Cooling to Room Temperature—Elastic Limit Can Be Made to Approximate Ultimate Strength by Overstraining Successively at Blue Heat With Gradually Increasing Loads

By H. J. French, Physicist, Division of Metallurgy, Bureau of Standards

COLD-WORK increases the elastic properties[1] of steel at ordinary temperatures and to a smaller degree the tensile strength, with an accompanying decrease in ductility. The greater the total reduction by cold-work within the capacity of the material the greater is the increase in strength. The tensile properties of steel at elevated temperatures are likewise modified. Jeffries[2] reports increased strength at blue-heat (200 to 300 deg. C.) after Armco iron has been drawn at room temperature with moderate reductions, but with 96 per cent reduction by cold-drawing the tensile strength is greater at room temperature than at any higher one.

Cold-Rolled Boiler Plate

The tensile properties at various temperatures of cold-rolled firebox and marine grades of boiler plate as determined by the author[3] are shown in Fig. 1. Comparison with curves 1 and 2 of Fig. 2, reprinted from the previous article, indicates that $\frac{1}{16}$ in. cold-reduction, approximating 12.5 per cent of the original plate thickness, increases the tensile strength at room temperature about 20 per cent, a margin which is maintained up to about 465 deg. C. (870 deg. F.), showing that this cold-working effect is maintained until relatively high temperatures are reached.

The changes in proportional limit are more marked and of considerable interest. At ordinary temperatures there is an increase of 80 to 95 per cent. Similarly an increase of 60 to 100 per cent above the values obtained in tests of hot-rolled plates is found at temperatures up to and including 245 deg. C. (470 deg. F.). In the blue-heat range [295 deg. C. (565 deg. F.)] the increase in proportional limit due to cold-work reaches the very high value of 150 per cent in the marine plate and nearly 200 per cent in the firebox grade. This, however, is not accomplished at the expense of ductility, as the elongation, which was reduced by one-half at room temperature, equals that of hot-rolled marine plate when tested at 295 deg. C. The relation between reduction of area of cold- and blue-finished marine steel has likewise increased to some extent, while that for the firebox grade has decreased somewhat slightly.

Effect of Tempering Cold-Rolled Plate

In order to determine whether these changes at blue-heat are maintained at ordinary temperatures specimens were tempered at successively increasing temperatures and then tested at room temperature. The results, which are represented in Fig. 3, illustrate, so far as the tensile properties are concerned, the benefits derived from "bluing" cold-finished products such as thin-wall seamless steel tubes. A short tempering in the blue-heat range, 295 deg. C. (565 deg. F.), materially increases the elastic ratio with little effect on the other tensile properties. This firebox steel had its limit of proportionality increased about 20 per cent. It is likewise apparent that a short tempering at somewhat higher temperature accomplishes little improvement.

Blue-Rolling

Working steel in the ranges where temper-colors are produced has long been considered deleterious and even dangerous. Stromeyer[4] warns against such practice, referring to his series of tensile and bending tests on iron, mild and hard steels, and writes: "It is very common practice amongst boiler-makers to 'take the chill out of the plate' if it requires a little setting, or to set a flanged plate before it is cold. This is really nothing else than working it at a blue-heat and should not be allowed. . . . All hammering or bending of

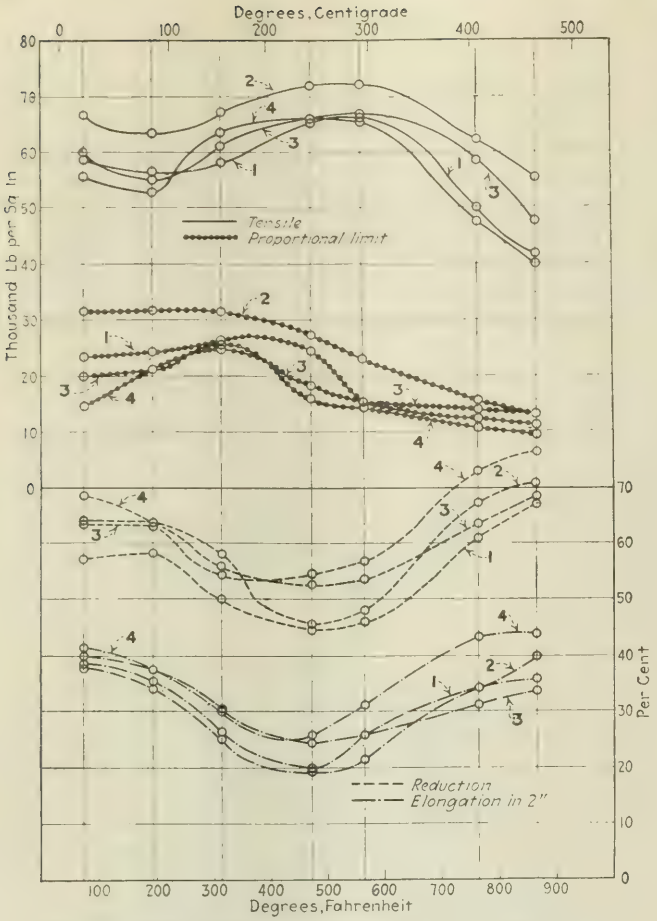

FIG. 2—TENSILE PROPERTIES OF FOUR HEATS OF BOILER PLATE MADE OF OPEN-HEARTH STEEL

iron and steel should be avoided, unless the metals are either cold or red-hot."

Howe in the 1891 edition of his "Metallurgy of Steel" summarized available information relating to what he calls "blue-shortness" and states in part: "Not only are wrought iron and steel much more brittle at a blue-heat[5] than in the cold or at redness, but while they are probably not seriously affected by simple exposure to blueness, even if prolonged, yet if they be worked in this range of temperature they remain extremely brittle after cooling. . . ."

"The loss of ductility as measured by endurance of bending and drifting is enormous; that this is not due to incipient cracks is shown by the simultaneous increase of tensile strength and by the restoration of ductility by annealing. The effect of blue-working on ductility as measured by elongation (on rupture by static tensile stress) is very irregular and apparently anomalous. . . . Heating to redness may completely remove the effects of blue-working."

Howe further called attention to the resemblance between the effects of cold-working and those of blue-working and that the immediate effect of these two operations might be suspected to be identical in nature.

Ridsdale[6] referred to blue-heat [315-370 deg. C. (600-700 deg. F.)] as the state of minimum plasticity and showed that soft steel developed brittleness when worked or soaked in a furnace for a long time in this range. He further pointed out that by reheating to a suitable temperature the good qualities of such steel were restored.

Jeffries[2] has studied the effects of blue-work on the tensile properties of Armco iron and reached the following conclusions:

1. Armco iron deformed at room temperature a given amount does not increase as much in tensile strength as when deformed the same amount at blue-heat.
2. The effect of drawing Armco iron at 200 to 400 deg. C. is to produce greater tensile strength at all temperatures up to 550 deg. C. than would obtain with the same amount of deformation in the cold. The elongation is less after drawing at 200 to 400 deg. C. than after drawing at room temperature. The same conclusion is true, in general, of the reduction of area.

While there seems to be unanimity of opinion that blue-work is deleterious to steel, Howe early called attention to the fact that "millions of car axles, blued from 'hot-boxes,' are chilled with snow and jarred under heavy load at loose rail joints, yet are apparently unharmed. Among the many thousand steel boilers tens of thousands of plates must have been worked more or less at blueness; yet failures are rare."

More recently it has been questioned whether crankshafts for airplane engines can be safely straightened while cooling from the tempering heat.

Plates Rolled at 300 Deg. C.

In order to determine the effect of permanent deformation at blue-heat on the high-temperature properties of boiler plate several pieces of railway firebox steel[3] (series 4) were reduced at about 300 deg. C. from $\frac{1}{2}$ in. to $\frac{15}{32}$ and $\frac{7}{16}$ in., representing respectively 6.25 and 12.5 per cent reduction. The patterns were rolled in a single stand 16-in. mill, a number of light reductions to effect the totals mentioned above being used. An attempt was made to straighten some of the plates cold and also at blue-heat immediately after rolling, but they broke transversely with a very coarse crystalline fracture as soon as pressure was applied. Comparison between curves 4 of Fig. 2 and Fig. 3 shows:

1. The increase in strength at room temperature resulting from cold-reduction of 12.5 per cent (Figs. 2 and 2) is about the same as that produced by half the

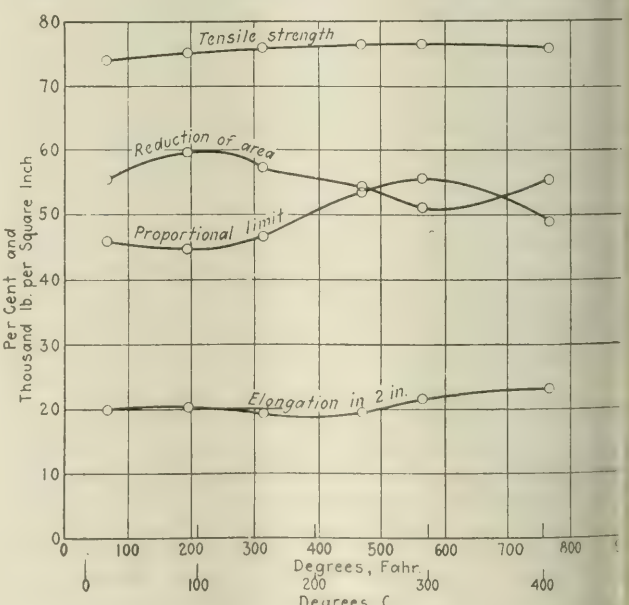

FIG. 3—EFFECT OF TEMPERING COLD-ROLLED BOILER PLATE (FIREBOX GRADE)

[5] The terms blue-work, blue-shortness, etc., as used by Howe, refer to temperatures where ordinarily temper-colors are obtained and may be considered to be within the range 220-320 deg. C. (430-600 deg. F.).

[6] "Correct Treatment of Steel," *J. Iron and Steel Inst.*, 1901, No. 2, p. 52.

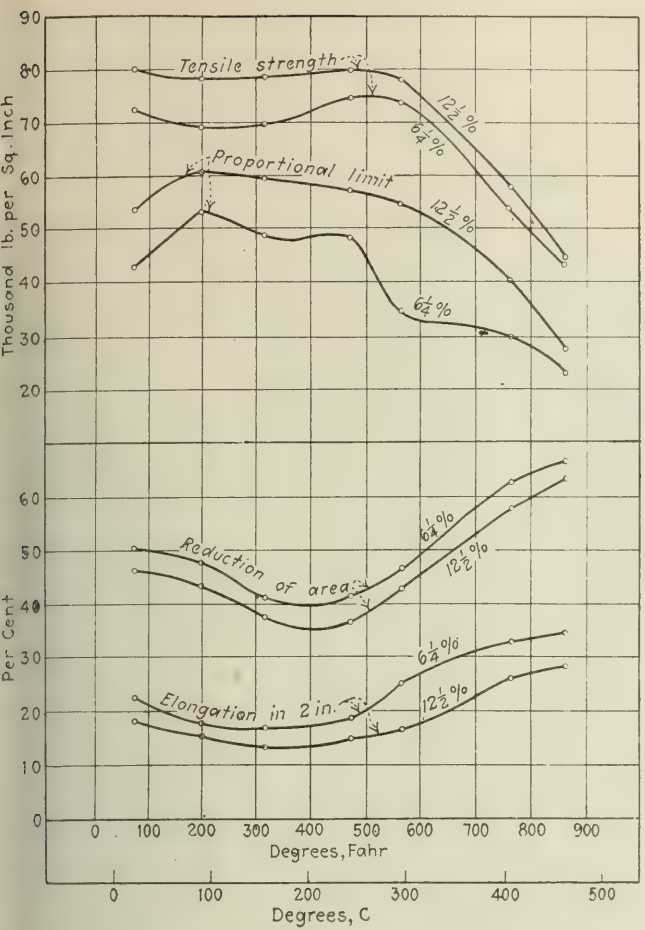

FIG. 4—TENSILE PROPERTIES OF SERIES 4 FIREBOX STEEL AFTER ROLLING AT BLUE-HEAT

eduction (6.25 per cent) at blue-heat (Figs. 2 and 4). This, in general, is also true at temperatures up to 295 eg. C. (565 deg. F.) (blue-heat). Above this temerature the increase in strength resulting from blueeformation is somewhat less than that from cold-rolling.

2. A "blue-reduction" of twice the amount does not ncrease the strength at room or elevated temperatures roportionally.

3. At 245 deg. C. (470 deg. F.) the strength of the lue-worked steel is little in excess of that hot-rolled.

4. The maximum tensile strength of the steel subected to 6.25 per cent blue-reduction is obtained at lue-heat [295 deg. C. (565 deg. F.)] and the shape of ne tensile strength versus temperature curve shown n Fig. 4 is similar to that for the cold-rolled steel Fig. 1). Tensile strength versus temperature curves nange direction quite abruptly at or about 295 deg. C. 565 deg. F.).

5. The increase in the limit of proportionality at oom temperature resulting from 6.25 per cent blueeduction is greater than that obtained from twice as uch cold-reduction. This is also true up to 245 deg. . (470 deg. F.), above which the increases are about qual.

6. The form of the proportional limit versus temerature curve for steel reduced 6.25 per cent at blueeat is similar to that reduced twice this amount in ne cold, but the secondary increase (which in the old-worked steel appears to attain its maximum at out 340 deg. C.) occurs at 245 deg. C. in the blueorked metal. This inflection is not observed in the eel subjected to 12.5 per cent blue-reduction.

7. Elongation and reduction of area decrease to a minimum in the neighborhood of 200 deg. C. (410 deg. F.) and thereafter increase to high values at 465 deg. C. (870 deg. F.). There appears to be a more rapid increase in elongation between 295 and 410 deg. C. (565 and 770 deg. F.) coincident with the rapid decrease of proportional limit mentioned above for steel reduced 6.25 per cent at blue-heat.

The effect of partial annealing of blue-worked steel is shown in Fig. 5. The proportional limit decreases until an annealing temperature of about 500 deg. C. (930 deg. F.) is reached, but annealing with slow cooling up to about 600 deg. C. (1,110 deg. F.) greatly increases the elastic ratio. Annealing for 30 minutes at about 730 deg. C. (1,345 deg. F.) completely removes the effects of blue-deformation.

Depth of Penetration of Effects of Blue- and Cold-Rolling

Since the effects of blue- and cold-work are so marked and maintained over a considerable temperature range, the question naturally arises as to whether the increased strength of the plate is due to hardening of the "skin," or whether the magnitude of the observed effect is substantially the same throughout the cross-section of such light plates as are under investigation.

The surfaces of cold- and blue-rolled bars were accordingly milled to progressively increasing depths and tested in the usual manner at room temperature, and it was found that there is substantially no difference in the strength when even a considerable depth of surface metal has been removed. Ductility (elongation and reduction of area) gradually decreases with removal of increasing layers of metal, due no doubt to the decrease in thickness of the specimen while the width has been kept constant.[7]

Transverse Strength at Various Temperatures

Tests of longitudinal specimens taken from plates rolled at various temperatures do not fully define the effects of such work, even when considering only the tensile properties. Accordingly tests were made on samples taken transversely from hot-, cold- and blue-rolled firebox steel of series 4. The results are given in Fig. 6.

[7] H. L. Moore, "Tension Tests of Steel With Test Specimens of Various Size and Form," *Proceedings*, American Society for Testing Materials, 1918, part 1, p. 403.

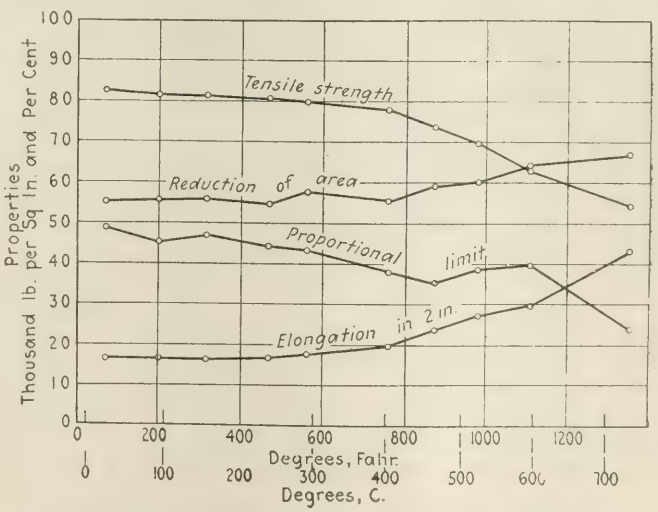

FIG. 5—EFFECT OF TEMPERING AND ANNEALING BLUE-ROLLED BOILER PLATE. (FIREBOX GRADE)

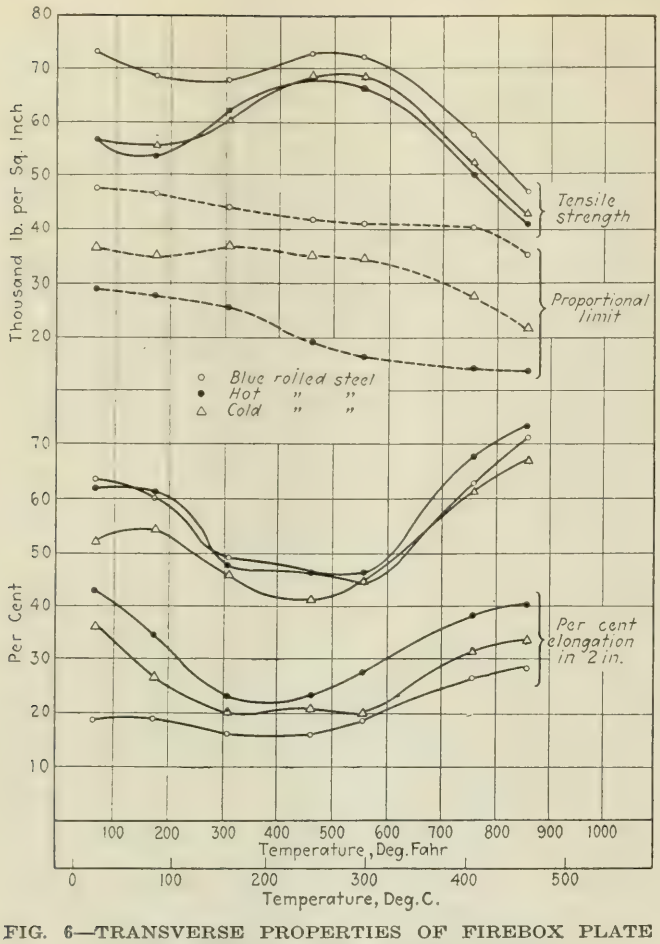

FIG. 6—TRANSVERSE PROPERTIES OF FIREBOX PLATE AT ELEVATED TEMPERATURES AFTER VARIOUS WORKINGS

It is at once evident that the general form of the tensile curves is similar to those for longitudinal tests with the exception of the limit of proportionality, which does not increase with first rise in temperature. Duplicate determinations do not agree as well as those obtained under similar conditions in longitudinal samples. The increase in transverse tensile strength at room temperature resulting from blue- or cold-rolling is very much less than that observed in longitudinal tests for the same mechanical reductions. Similarly the increase in proportional limit and decrease in ductility resul ing from deformation at room temperature or blue-hea are less than the effects observed in longitudinal test The proportional limit of steel deformed cold or a blue-heat is raised more than is the transverse strengt but this difference is not so marked as in tests made o longitudinal samples.

Permanent Deformation Produced by Stretching

Huston[8] found that in loading bridge iron to ju above the "so-called elastic limit" the ductility or toug ness remained unaffected so that the metal would yie with every small increase in load. When stressed ju below that point, the iron became rigid and would n elongate without a decided load increase.

From a large number of tests of wrought iron a low-carbon steel Bauschinger found that when subject to overstrain at ordinary temperatures certain thin occurred: When stretching was produced by a lo between the proportional limit and yield point, t former was raised. An applied stress greater than t yield point resulted in a decrease in the limit of pr portionality, a loss which was recovered upon agi for a long time at room temperature or for short periods at higher temperatures. This aging effect w counteracted by high heating, but the method of co ing was observed to play an important part—high he and rapid cooling being most effective. Aging aft heating and cooling exerted no further effect.

Howe ("Metallurgy of Steel") reported that stret ing at room temperature lowered the limit of prop tionality of steel, often to zero. The effect of rest w slowly to restore the elasticity and finally raise it abo the load that caused the previous deformation, but t occurred more slowly at room temperature than wh the steel was warmed.

Muir[9] found that the elastic recovery of overstrain steel was as marked after 3 or 4 minutes at 100 d C. as in 2 weeks at room temperature and was impe or entirely prevented at lower temperatures around deg. C.

Howard[10] stated that "the effect of straining hot

the subsequent strength when tested cold appears to depend upon the magnitude of the straining force and the temperature when overstrained. There is a zone of temperature in which the effect of hot-straining elevates the elastic limit above the applied stress and above the primitive value, and if the straining force approaches the present tensile strength there results a material elevation of that value when cooled. After exposure to higher temperatures a gradual loss occurs in both elastic limits and tensile strength, and generally there follows a noticeable increase in the contraction of area." Howard found the zone of elevation of the elastic limit had apparently been passed when the steel was subjected to overstrain at about 395 to 425 deg. C. (740 to 800 deg. F.) and noted the importance of time between overload at high temperatures and subsequent test.

Because of the extended field for research along these lines the tests of overstrained steel noted in Table I made by the author were limited to the region about the blue-heat, for the most marked changes in tensile properties have been found in this temperature range.

At blue-heat [295 deg. C. (565 deg. F.)] tensional stress in excess of the limit of proportionality raises this limit in a short time after release of load to a value approximating the stress producing the previous deformation (samples H26, 20 and 22); but when this stretching at blue-heat is followed by cooling to room temperature and subsequent test (sample 33) the immediate effect of the "blue-overstrain" is a lowering of the proportional limit.

Repeated overstrain at blue-heat, whether at constant or increasing loads, raises the apparent limit of proportionality at this temperature in a like manner and to a similar degree. The magnitude of this increase may be considerable. Sample H25 had its proportional limit raised from 15,000 lb. per square inch in steps to a little more than 56,000 lb. per square inch, or 375 per cent, by 22 loads constantly increasing in intensity.

TABLE II—CHANGES IN ELASTIC LIMIT IN COMPRESSION UPON AGING

—Tensional Stress Applied— Lb. Per Sq.In.	At Temperature, Deg. C.	Overload Beyond Proportional Limit, Lb. Per Sq.In.	Proportional Limit in Compression at Room Temperature* Time After Tensional Overstrain, Hours	Average Proportional Limit
45,000	20	13,800	28	13,250
			52	11,250
45,000	295	22,550	3	19,500
			6	19,800
			30	17,500
			49	17,000
			54	14,700
30,000	463	17,500	3	15,650
			29	17,650
			48	21,000
			71	24,000

* Size of compression sample: ¾ in. diameter, 1½ in. long. Gage length of 1 in. used. Samples cut from 1-in. marine boiler plate. Average compressive limit of proportionality at room temperature was 23,750 lb. per square inch. Two samples were tested for each age.

Such deformation does not, however, appear to modify the values of tensile strength, total elongation or reduction of area when the specimen is finally broken. These results appear consistent with Bauschinger's deductions and the work of others mentioned for a very rapid recovery from elastic overstrain; almost immediate elevation of the proportional limit would be expected at the temperature at which the stresses were applied.

Heating to a temperature above Ac_1 and thereafter cooling steel which has been overstrained at blue-heat (sample J19) immediately restores the apparent elasticity of the metal at room temperature. Such thermal treatment does not lower the limit of proportionality, which in a test at room temperature remains at a value approximating the previous overload at blueness.

Metal previously overstrained at moderate temperatures regains its elasticity after rest at room temperatures (samples J15, 18, 20 and 21). It is not quite clear whether the immediate effect is to destroy the elastic properties, but such is probably the case.

Rosenhain in his "Introduction to Physical Metallurgy" states that the hardening of steel by plastic strain is unidirectional and that a piece of steel which had attained an apparently raised proportional limit as a result of tensile overstrain was really weakened in compression. Therefore the total range of elasticity, from the limit of compression to that in tension, had not been materially altered. To test this deduction samples of marine boiler plate were subjected to stretching at several temperatures beyond the limit of proportionality and then tested in compression (Table II). The effect of such tensional overstrain at room temperature, blue-heat and about 465 deg. C. (865 deg. F.) is a lowering of the limit of proportionality in compression when tested at room temperature. When the steel is permitted to rest, the samples stretched at blue-heat or below show a gradual decrease in the compressive limit of proportionality as time passes by, a fact which, taken in conjunction with the rise in proportional limit in tension, indicates that the range of elasticity is not altered, but merely shifted. Steel similarly stretched at 465 deg. C. behaves differently, however, for with age the proportional limit in compression rises for 70 hours until it approximates its original numerical value.

Calculating the Gravity of Liquid Petroleum Products

Since publishing the announcement of the American Petroleum Institute's new scale for reporting the gravity of liquid petroleum products,[1] some question has arisen as to how this scale differs from Baumé standard for liquids lighter than water. As has been previously pointed out, the difference lies merely in the fact that the conversion modulus for the A.P.I. scale is 141.5 instead of 140.

The formula on which the standard American Petroleum Institute scale is based in terms of "degrees A.P.I." is as follows:

$$\text{True sp.gr. } (60/60^\circ \text{ F.}) = \frac{141.5}{131.5 + \text{deg. A.P.I.}}$$

$$\text{or Deg. A.P.I.} = \frac{141.5}{\text{True sp.gr.}(60/60^\circ \text{ F.})} - 131.5.$$

The formula on which is based the U. S. Baumé scale for expressing the true specific gravity of liquids lighter than water (other than petroleum) in "degrees Baumé" is as follows:

$$\text{True sp.gr. } (60/60^\circ \text{ F.}) = \frac{140}{130 + \text{deg. Bé.}}$$

$$\text{or Deg. Bé.} = \frac{140}{\text{True sp.gr.}(60/60^\circ \text{ F.})} - 130.$$

The relation between the two scales at 60 deg. F. is:

Degrees A.P.I. = 1.010714 Deg. Bé. — 0.10714

Thus 10° Be. (140 mod.) corresponds to 10.0 A.P.I. (141.5 modulus)
30° Be. (140 mod.) corresponds to 30.2 A.P.I. (141.5 modulus)
50° Be. (140 mod.) corresponds to 50.4 A.P.I. (141.5 modulus)
70° Be. (140 mod.) corresponds to 70.6 A.P.I. (141.5 modulus)
90° Be. (140 mod.) corresponds to 90.8 A.P.I. (141.5 modulus)

Metaldehyde as a Fuel

An Interesting Account of the Manufacture and Properties of a New Solid Fuel Developed for Household Use by Swiss Electrochemists

By H. Danneel

MANY types of solid fuel have appeared on the market. At the outset soaps were used as the solidifying medium for the alcohol to which shellac, stearine, tallow and stearic acid were sometimes added and from which the oleic acid was eliminated so as to obtain better burning. Subsequently collodion and cellulose acetate were used for solidifying the spirit[1] and also the jel made from agar agar.[2] Large quantities of these and similar fuels were used during the European war and some little post-war demand for them has been established because, in spite of their defects, they are more convenient to use than is liquid alcohol. The chief fault with most forms of solidified spirit is found in the volatility of the alcohol, which necessitates the use of air-tight vessels. Otherwise evaporation would take place and the calorific value of the fuel would be impaired. The fact that solidified spirit liquefies when ignited renders it unsuitable for many purposes and the residual ash is sometimes considered an objectionable feature.

Apart from the above, paraformaldehyde and hexamethylenetetramine have been recommended as fuels. After the flame of the former has been extinguished it gives off vapors of formaldehyde, not easily forgotten by anyone who came too close to them. Hexa was scarcely more than an emergency product during the war, for the cost of the raw materials formaldehyde and ammonia is comparatively high. Its cost is further increased by a manufacturing loss amounting to almost one-half of the raw materials. The characteristics of hexamethylenetetramine as a fuel are for the most part satisfactory, if objection is not taken to the fact that it is soluble in water. Certain other materials have also been recommended as fuels but have not acquired industrial importance.

A new and rather promising solution of this problem appears to have been arrived at recently by a Swiss firm, the Usines Electriques de la Lonza of Basel, which is producing a fuel from metaldehyde, a substance to which, up to the present, only scientific importance was attached. Its manufacture on a commercial scale has been rendered possible through the synthetic production of acetaldehyde from calcium carbide.

Discovery and Properties of Metaldehyde

Metaldehyde was discovered by Liebig,[3] its existence confirmed by Fehling[4] and its properties were investigated by Kékulé and Zincke.[5] It is formed as a by-product when acetaldehyde is transformed into paraldehyde by the action of acids or salts. At ordinary temperature a solution of very small quantities of metaldehyde in paraldehyde is obtained but at low temperatures small quantities of solid metaldehyde are obtained in the shape of fine white needles which can be increased in size if the process is carried on slowly.

Metaldehyde does not melt under atmospheric pressure and starts to sublime without melting between 11[illegible] and 115 deg. C. In a closed tube it is said to melt at 160 deg. C. (Roozeboom 184 deg. C., Hollmann 16[illegible] deg. C., Smith and de Loeuw 246 deg. C.). Metaldehyde when impure, gradually volatilizes in the form of acetaldehyde when left in the open air, particularly during hot weather. In confined spaces it changes into paraldehyde. When chemically pure, it is a substance of practically permanent stability. Its molecular weight corresponds to the formula $(CH_3COH)_4$. The heat of combustion amounts to about 6,000 cal. per kg.

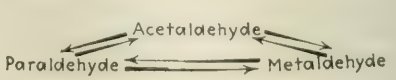
In the majority of solvents metaldehyde is but little soluble; for instance carbon bisulphide, acetone, glacial acetic acid and water. Acetaldehyde dissolves but 0.2 per cent at 19 deg. C., paraldehyde dissolves but 0.06 per cent at 12 deg., boiling alcohol 1.8 per cent, boiling ether 0.5 per cent and benzine at 23 deg. dissolves a maximum of 13.5 per cent.

Acetaldehyde-Metaldehyde-Paraldehyde Equilibr[illegible]

The interesting instance of three polymorphous substances, whose transformation into one another can be greatly accelerated by catalysts (pure acetaldehyde is known to keep for a long time without changing into paraldehyde), has invited investigations of the processes from a physical and chemical point of view. From these as well as from numerous tests made in connection with the commercial manufacture of metaldehyde, the following conclusions can be made:

1. If acetaldehyde is subjected to the action of catalysts at ordinary temperature, it polymerizes. The quantities of catalysts required are exceedingly small; 0.1 per cent and less has been found to suffice.

2. The polymerized substances formed are paraldehyde and metaldehyde and the reaction proceeds with a speed determined by the strength of the catalyst until an equilibrium is established, which equilibrium depends on the temperature but not on the nature of the catalyst. The reactions which lead to the equilibrium are three in number, that is to say—acetaldehyde ⇄ paraldehyde, acetaldehyde ⇄ metaldehyde, paraldehyde ⇄ metaldehyde—and might be illustrated by the schematic formula:



The reaction which starts from pure acetaldehyde to which has been added the necessary quantity of catalyzing agent leads at 15 deg. C. to a liquid mixture of the three substances in which paraldehyde predominates to the extent of about 92 per cent. Metaldehyde can clearly form to a very slight extent only, at [illegible]

vents in smaller quantities than are required for a aturated solution in paraldehyde (i.e. 0.06 per cent). n intermediate phases too, there are no visible signs f the formation of metaldehyde when the reaction roceeds at 15 deg., which proves that the quantity resent in these intermediate stages does not exceed hat which can be taken up by acetaldehyde, that is to ay 0.25 per cent.

3. At low temperatures the circumstances are different. The solubility of metaldehyde in acetaldehyde ecreases with the temperature, and by a judicious hoice of catalysts it can be brought about that temorarily more metaldehyde is formed than can be reained in solution by acetaldehyde or by paraldehyde, n which case metaldehyde would be precipitated as a olid body. The final equilibrium, however, would not n any way be altered, so that toward the end of the eaction the precipitated metaldehyde would again disappear. There are a number of substances which ppear relatively to accelerate the reaction. Acetaldeyde → metaldehyde to a greater extent than the imultaneous reaction acetaldehyde → paraldehyde. Only such substances, of course, are of value in conection with the manufacture of solid metaldehyde, nd among them are nearly all of the strong acids, particularly sulphuric acid and also a few salts. It is clear that the reaction product must not be left to itself too long and that the process has to be interrupted when the maximum quantity of metaldehyde as been formed, because otherwise it would practically disappear again.

Manufacturing Difficulties

In the course of manufacture a number of difficulies are met with, some of which it has not been found an easy matter to overcome. First of all, there is the selection of the best catalyst. A given substance can influence in different ways the three reactions which have to be considered. It can, for instance, accelerate reaction 1 and exert no influence on 2 and 3, or even retard them. It can accelerate all three reactions or two of them, leaving out the third one, so that from a mathematical point of view, 24 combinations are possible. Moreover, the effects of the catalyst are modified in various ways by the temperature. Cases are known where a catalyst does not act at a temperature below 10 deg. C., but exerts a very marked action at higher temperatures. A much stronger action in fact than might be expected from the temperature coefficient of the speed of reaction, which is generally assumed to be 1/5. Ultimately the solubility of metaldehyde in paraldehyde, acetaldehyde and mixtures of these two depends on the temperature and determines the precipitation of metaldehyde. Its dependence on the temperature, however, is not the same as that of the efficiency of the catalysts. When working at very low temperatures, there is also the risk of paraldehyde, which has a solidifying point of 12.5 deg. C., solidifying. Therefore it would appear that although metaldehyde is metastable at ordinary temperature, it has to be guarded during the course of manufacture against transformation into paraldehyde or acetaldehyde.

The regulation of the temperature during the manufacturing process is not a simple matter. The reaction is exothermic and in large reaction vessels the temperature can easily rise locally. Unless it is distributed at once a local acceleration takes place in the formation of paraldehyde, accompanied by further rises in the temperature, so that the reaction may assume the nature of an explosion. Within a few minutes the total contents of a large reaction vessel may be brought to the boiling point, an occurrence which has to be guarded against by all means, in view of the flammability of acetaldehyde.

Preparing It for the Market

When the maximum quantity of metaldehyde has been precipitated, the reaction product is treated in a hydro-extractor and freed from the liquid, which consists mainly of paraldehyde with small quantities of acetaldehyde. This liquid is transformed into acetaldehyde and again enters the process unless it is desired that it be worked up into pure paraldehyde.

Metaldehyde, such as it is obtained in the above process, is not suitable for consumption as a fuel. It consists of small needles, the size of which is inversely proportional to the speed of formation. When dry, it forms a voluminous powder which so readily ignites that its use would involve some risk in the household. It moreover develops a strong flame and burns away quickly, so that it is impossible to utilize fully its calorific value. By compressing it strongly into convenient shapes, it has been found possible[7] to render it suitable for the purpose in view. When so treated, metaldehyde does not ignite as quickly as alcohol, but requires a few tenths of a second's contact with the flame of a match.

Shaped metaldehyde exhibits peculiar symptoms when burning. It is not the metaldehyde itself which feeds the flame, but acetaldehyde which is formed from it by the heat radiated by the flame. The fuel, therefore, is surrounded by a zone of cool gas which prevents the flame from touching the fuel itself. This, together with the absorption of heat necessitated by the transformation of metaldehyde into acetaldehyde, keeps the fuel itself cool, so cool in fact that it is possible to extinguish the flame by the palm of the hand without risk of injury from burning. The transformation into acetaldehyde during the burning process regulates itself; as soon as volatilization becomes more intense the flame is removed from the solid block and there is less radiated heat and the volatilization is automatically checked. Compressed metaldehyde is characterized by its steady and uniform flame.

Why Impure Compound Is Most Satisfactory

The influence of the catalyst during the combustion process is more noticeable in connection with metaldehyde than it has been with any other kind of fuel. When metaldehyde such as comes from this process, that is to say in an impure condition, is pressed into shapes, the resulting fuel exhibits traces of the characteristic acetaldehyde smell, even when not exposed to heat. This indicates that a slow decomposition of metaldehyde is taking place. This smell becomes very marked during a few minutes after the flame has been extinguished, a thing that would not happen with pure metaldehyde. This is due to the action of minute particles of the catalysts adhering to the metaldehyde crystals. These impurities can scarcely be measured and probably amount to only a few millionths of a per cent, so that an elimination would be much more troublesome than other means to counteract the influence of the catalyst. Such means would consist in depriv-

[7] Metaldehyde compressed as fuel patented in 20 countries. Br. Pat. 144,589, Swiss Pat. 84,746, U. S. Pat. 1,407,101.

ing the catalyzing agent of its efficiency by neutralizing the acid and transforming, for instance, sulphuric acid into barium sulphate, hydrochloric acid into silver chloride, or by treating sulphuric acid with ammonia and transforming it into ammonium sulphate, which is inert. Another way would be to eliminate the liquid phase—a course which is facilitated by the fact that metaldehyde is neither hygroscopic nor soluble in water.

But supposing metaldehyde were entirely free from a catalyzing agent, such as could be obtained by sublimation in a vacuum, or recrystallization, or such as would be obtained by depriving the catalytic agent of its efficiency, the combustion would show new and undesirable phenomena. Such a pure product ignites only with difficulty and, in contrast with the impure product, the flame touches the fuel, which becomes hot, and when extinguished, clouds of sublimed metaldehyde can be noticed floating in the air in the shape of a fine fluff. Moreover, the sublimation would tend to clog delicate parts of a burner, such as the delicate regulating devices used in some applications.

It is evident, therefore, that for a metaldehyde fuel a catalyzing agent is required to influence the combustion process, while for the storage of the fuel it is not wanted and not even desirable. For that reason a means has been found to render the catalyst inert at temperatures below 30 to 40 deg. C., and at the same time allow its active properties to become evident at temperatures of 60 deg. and above. This temperature is produced by the heat radiated from the flame, and when the flame is extinguished and the temperature falls the catalyst again becomes inert. In that way it has been found possible practically to do away with the odor, which for that matter might have been disguised or modified by the addition of certain scenting materials. Furthermore, this is accomplished without interfering with the desirable effects on the combustion process.

Rapid Methods for Determining Endurance Limits

A report of progress from the British National Physical Laboratory (abstracted in *The Iron and Coal Trades Review* for June 30, 1922) notes that the method of predicting fatigue ranges of stress which has hitherto been employed at the laboratory has been by means of a series of tests on different specimens (usually six) at different ranges of stress, commencing with a range well above the fatigue limit so that fracture occurs after a comparatively short number of reversals, and then progressively diminishing the range of stress for the other specimens until fracture fails to occur with a number of reversals of the order of five to ten millions. It is then comparatively easy by means of plotting to predict the limiting range of stress. This method, although otherwise satisfactory, is slow and costly and several attempts have been made by workers in this field to predict the fatigue range of stress from a test on a single specimen of the material. One method is that due to Dr. J. H. Smith, who has found that by attaching an optical extensometer to a specimen under reversals of tensile stress, the stress-strain curve obtained, under gradually increasing range of stress, exhibits a "yield-point" characteristic similar to that found in static tests, and that the range of stress corresponding to this yield point is the true fatigue range of the material.

A calorimetric method has been devised by Mr. Stromeyer for use in alternating torsion tests. I this method the specimen under test is water-jacket and the temperature of the circulating water carefull observed. The torsional fatigue limit is determined b noting the stress at which a small but perceptible ris of temperature of the jacket water due to the heatin of the specimen by internal work takes place. In th experiments carried out during the year both of the methods were used simultaneously on the same specime under alternating tension, the chief modification bein that instead of using a water jacket the temperatu of the specimen was determined by a thermo-junctio Satisfactory agreement between the two methods ar the results of fatigue tests on the material by th ordinary Wöhler method have been obtained for the ca of a wide range of materials.

The method of "yield ranges" has also been extend to tests on specimens subject to reversals of bendi stress in the ordinary Wöhler fatigue testing machin A plane mirror is mounted on the end of the specim with its plane perpendicular to the axis of rotatio The changes in the slope of the plane of the mirr due to gradual increases of the load on the specime are observed by means of a source of light and a lo optical lever (40 yards in length). On plotting t results on a base of stress range a "yield point" c be detected at a stress range which is identified wi the fatigue range of the material. By means of the methods the time necessary to predict the limiting ran of stress has now been reduced to less than half an ho

Phosphorescence

Sir George Beilby, in his recent book on "Aggregati and Flow of Solids," describes a number of experimen going to show that certain types of phosphorescence a due to the molecular movement or displacement whi is produced by heat, by mechanically applied stresses by radiant energy. Certain other types of ph phorescence are distinguished by their appearance three stages, called by him primary, secondary and r vived phosphorescence. These can be explained as d to atomic changes in which chemical affinity is t controlling factor. Furthermore, a species of el trolysis occurs in solids exposed to the beta or catho rays; the products of electrolytic dissociation are ins lated or partly insulated from each other by the neut molecules as in a viscous electrolyte; and it is t breaking down of this insulation and the recombinati of the ions which cause revived phosphorescence.

Forging and Working Invar

Invar steel is very difficult to work mechanically b is an important alloy for certain classes of work whe very low coefficient of expansion is desired. In ord to see whether it could be worked successfully, fo small ingots of invar were prepared by the Metallurgi Division of the Bureau of Standards. The first attem at forging was unsuccessful, the ingot cracking a breaking under the forging press. The second attem was quite satisfactory as a result of very care handling during forging operations.

It was found necessary to give very light reductio and not allow the forging temperature to drop bel 1,000 deg. C. during the first reduction. This ingot w forged to a $\frac{3}{8}$-in. rod, and a portion of this was cut and machined to a $\frac{1}{4}$-in. rod. This has been cold dra with two intermediate annealings down to approximat $\frac{1}{16}$-in. wire.

Chemical Lead And the Causes of Its Technical Failure

An Analysis of the Effect of Various Impurities on Physical Properties and Technical Value of Chemical Lead

By Thomas French

DURING the last 50 years a considerable amount of research work has been devoted to "chemical lead." Although many facts with examples of faulty lead have been collected and many theories have been formed to account for the defects commonly occurring in lead, much still remains to be done, especially work of an academic nature. At the time Percy published his metallurgy of lead, in 1870, both the Pattinson and Parkes processes for the desilverization and purification of lead were in general use, and although the reasons underlying the separation of the various impurities in each case were not then so well established as they are now, the practical application of the processes was much the same as at the present day.

Parkes vs. Pattinson Process of Lead Refining

At all the large smelting works, desilverization by the Parkes process is almost universal on account of its lower cost, but there are still a few of the smaller smelting works in Europe that retain the Pattinson process because of the simplicity of its operation. Still more of the refiners of lead, not necessarily smelters, retain the Pattinson process in order to refine the lead to the grade required for the manufacture of white lead by the Old Dutch process, for which it is necessary to have a very highly refined lead, and in a lesser degree for the manufacture of red lead and litharge. Litharge for assayer's purposes, in which the silver has been reduced to a few grains per ton, is also made from lead that has been desilverized by the Pattinson process.

Effect of Addition of Bismuth to Purified Lead

There are certain elements that are not removed in refining lead by the Parkes process, notably bismuth, which unfortunately ranks as the most objectionable of all the impurities that occur in lead. Lead of "corroding" grade is generally required to contain not more than 0.05 per cent of bismuth. It is doubtful, however, if bismuth has the bad effect on white lead that is so often attributed to it. White lead of the best quality has been made by the Old Dutch process from an otherwise highly refined lead but containing more than 0.1 per cent bismuth, which was purposely added, with no observable bad effect or retardation of the corrosion. It is said, however, that the bismuth becomes concentrated in the residue of lead that remains after corrosion has stopped and that the grooves in the flat grinding stones quickly become filled with it, making grinding difficult. For other white lead processes such highly refined lead as is used for the Old Dutch and chamber methods is not necessary. For the manufacture of red lead and flake litharge, the bismuth content of the lead must be low, otherwise the color will be dirty and the flake litharge will not break down properly on weathering, resulting in a large proportion of hard lumps which must be sold at a less profitable price.

For concentrating sulphuric acid by means of lead pans there is not the slightest doubt that bismuth causes the acid to attack the lead at a very much lower temperature than when purified lead is used, and although it has by no means been definitely proved, the opinion is general that in "chamber" lead its presence is also very undesirable.

The cost of refining lead or desilverizing by the Pattinson process is somewhat more than by the Parkes process. This is unfortunate, as the Pattinson process removes bismuth from the lead and concentrates it in the uncrystallized portion containing the silver and other impurities. On the other hand, the Pattinson process removes copper very imperfectly, while the zinc used in the Parkes process has a great affinity for copper. For both processes the removal of copper is effected by a particular modification of the softening or improving process, previous to the desilverization. American lead is usually contaminated with bismuth to a much greater extent than European or Australian lead and were it not that the cost is more, the Pattinson process would be much more suited to the refining of American lead than the Parkes process. Should the demands of the user of lead become more exacting with regard to the presence of bismuth, it is possible that the American smelter may be forced to use a combination of the Parkes and Pattinson process. It is probable that the cost of the Pattinson process may be considerably reduced by a different and simpler arrangement of the plant than that of the Rozan and more modern modifications.

Variation in Analyses of the Same Lead by Different Men

There is very little information published as to the extent to which lead may be purified by either the Pattinson or Parkes process. It is generally understood that with the exception of bismuth, Parkes lead is purer than Pattinson and it is probably the case that for an equal removal of silver in an ordinary refined lead, Parkes lead is purer. There can be little question, however, that for extreme purification the Pattinson process is superior to the Parkes, judging mainly by the physical properties of the extremely refined leads.

It is a costly and by no means an easy matter to make a reliable analysis of a refined lead. When it is remembered that the total impurities comprising probably a dozen ingredients may amount to less than 20 mg. when 200 g. are used for analysis, the difficulty will be more readily appreciated. Some of the impurities, such as bismuth for instance, may be determined with a fair degree of accuracy. Silver by the cupellation method is held by many to be more accurate than by wet analysis. If each constituent could be gone after individually from a fresh solution of the lead there would be some chance of obtaining an accurate result, but when one after another of the constituents is determined in the same solution, with so many evaporations, the use of reagents which are by no means as pure as might be expected and with contamination by dust and the other things incidental to an analysis, the final result can be only approximately correct. It is,

in fact, quite common to obtain from different analysts analyses of the same sample of lead that have only the remotest likeness to one another. A. G. Betts, in his "Lead Refining by Electrolysis," gives examples of analyses of the same sample of lead, by three chemists, as follows:

PER CENT OF IMPURITIES

	Fe	Zn	Sb	Cu	As	Bi	Ag
A	0.00023	0.0004	0.0007	0.00043	0.00005	None	0.00003
	0.00032	.....	.....	0.00045	.....	....	.....
	0.00040	.....	.....	0.00045	.....	....	.....
B	0.0022	0.0079	0.0013	0.0013	0.0065	....	0.00016
C	0.0037	0.0042	0.0007	0.0012	0.0092	....	0.0003

Another example quoted by the same author of a sample analyzed by two analysts is as follows:

PER CENT IMPURITY

	Cu	Sb	Fe	Sn	Ag
A	0.0003	0.0060	0.0003	0.0049	0.0006
B	0.0020	0.0010	0.0046	0.0095	0.0006

In the latter instance it will be noticed that as regards copper, A's result is nearly 7 times less than B's; antimony, 6 times more; iron, about 15 times less, and tin about half as much, while silver, which was probably determined by dry assay, is the same in both cases.

An analysis of a refined lead, including a blank of the reagents used, usually requires about three weeks to perform. The difficulty, unreliability, time and expense of making an analysis of a refined lead are no doubt among the principal reasons for the small advance that has been made in our knowledge of the properties of lead.

Remarkably Consistent Properties of Lead From Different Refineries

It is remarkable how invariable the different well-known brands of lead on the market are as regards their physical properties. Australian "Brokenhills," Spanish "Pennaroya" and Perth Amboy leads each have their own characteristics which remain unchanged over a long period of years. Considering the variety and impurity of the ores from which the lead has been derived, the constancy of the refined lead must be admitted to be largely due to the particular method of treatment that the work lead has undergone as regards softening previous to desilverizing, method of desilverizing and subsequent refining. None of these leads is capable of resisting the action of 96 per cent sulphuric acid at the boiling point of the acid. Before that temperature is reached the lead is violently converted into sulphate of lead and sulphur is deposited, with the evolution of sulphurous acid and hydrogen. After subjecting these leads to further purification by the Pattinson process they are almost unaffected by the boiling acid, only a few bubbles of gas being observed and almost no conversion of the lead into sulphate after a considerable time. Usually, four crystallizations of the lead are sufficient to give this result and a further crystallization through another four pots makes little difference, although the physical properties of the lead are thereby improved.

Lead when refined to this degree solidifies in the mold into which it is cast with a highly colored surface characteristic of pure lead and with the crystals on the surface very well defined and in large aggregates. When a small sheet of this lead that has been cast into a mold and not rolled is subjected to the action of dilute nitric acid, these aggregates of crystals are slowly eaten around, the eutectic being eaten away more rapidly than the crystals. Lead has the power of dissolving oxide of lead when very hot. This oxide of lead is given up very completely when the lead is slowly cooled, but it may be that a minute quantity separates between the crystals and is attacked more readily by the acid.

Addition of Impurities to Refined Lead

If this highly refined lead, crystallized eight times, is alloyed with a small quantity of another metal to the amount of about 0.1 per cent, the action of the nitric acid is increased and a difference in the behavior of the metal added is discernible. That with antimony dissolves most rapidly and is accompanied by a black deposit; bismuth comes next, then copper. Arsenic and silver are very nearly equal to copper. Zinc, cadmium, tin and sodium are a little better than copper, and the alloy with aluminum is best of all.

When subjected to the action of strong sulphuric acid the alloy with bismuth is attacked when only moderately heated and if the heating is continued the lead is violently converted into sulphate. The alloy with silver and that with antimony come next and are violently attacked. Arsenic stands the action much better than silver and antimony. Cadmium, tin, aluminum, copper and sodium are about equal and still better, while zinc stands the action better than all the others.

Tests such as these on alloys of very pure lead with a very small quantity of another individual metal are, however, of little value for practical purposes, for when more than one metal in small quantity is added to the lead, the action of the acid appears to be quite different. The one metal apparently has an inhibitory or corrective effect on the other. Thus, when copper is present along with bismuth, it withstands the action of the acid very much better. This has been dealt with by D. W. Jones,[1] who gives the effect of the addition of various small amounts of copper to chemical lead. It should be remembered, however, that the chemical lead with which he experimented is of a much more impure quality than the highly refined lead referred to above.

Failure in Sulphuric Plants Often Due to Poor Management

The causes of failure due to defective lead are very varied. Lead used for chamber work may be quite satisfactory, while the same lead used in a concentrating pan may be worthless. For chamber work the sheet lead may have local defective parts which shorten its life, but usually the life of a chamber depends on the extent to which the production of acid is forced and on the management. Of two plants using exactly the same sheet lead for the construction of sulphuric acid chambers, one usually produced about four times as much sulphate of lead as the other.

The principal cause of the solution of the lead is generally considered to be the presence of an excessive quantity of nitric acid, in place of nitrogen trioxide and peroxide. If this is so, a pure lead should stand the action much better than an impure lead, but this deduction must be modified by the fact that the presence of air will accelerate the action, whereas the surface film of sulphate of lead that is formed will decrease it. Thinning of the sides of the chamber usually takes place near the top of the chamber and near the bottom. Sheets have been rolled thicker at the top and bottom for this reason, with good results. Pitting and roughening of the sheets is a very common defect and long irregular corroded channels

[1] *J. Soc. Chem. Ind.*, vol. 39, p. 221 T.

imilar to those often met with in lead pipes that have een lying underground, subject to electrolysis, are also ommon. Analysis of the lead in these cases gives little nformation as to the cause of corrosion. In any case, ne analysis of one part of a sheet of lead may be uite different from that of another part, for the im-urities in a block of cast lead are not disposed equally nroughout its mass. The end sheets rolled from the lock may be very different from the middle, as regards istribution of the impurities.

Behavior of Lead in Concentrating Pans

In concentration pans the acid is kept at a tempera-ure very little above 200 deg. C., while the melting oint of lead averages about 325 deg. C. Pans often ive way suddenly after a few days' use and sometimes nly after they have been in use for a long period. he contents of the pan suddenly become milky through ne formation of sulphate of lead and sulphur, accom-anied by a rise in temperature, and a large hole is apidly eaten through the pan. The addition of cold eak acid appears only to aggravate the action, prob-bly on account of the heat developed. Usually in such ases the cause will be found to be the presence in the ead of either bismuth or antimony.

William Beaumont Hart gives an example[2] of a an which he states was made of Pattinson lead hich had been crystallized three times, and contained, mong other impurities, a trace of antimony, 0.003 er cent bismuth and 0.0014 per cent copper. Five ays after starting the pan, without any known cause nd without evolution of gas, the pan started to leak. s contents became milky and a gradual slow action as observed. The remaining contents of the pan were nalyzed, showing the acid to have a specific gravity f 1.551 at 15 deg. C. and a strength of 63.8 per cent ulphuric acid. Among the impurities present in this cid there were bismuth 0.2247 per cent; zinc 0.0759 er cent; copper 0.0941 per cent; silver 0.0471 per cent, nd a trace of antimony. From the cubic capacity of ne cavities that had been eaten away he calculated nat the original lead at these parts must have had a ercentage composition as follows: Bismuth, 0.1250; opper, 0.0523; silver, 0.0262; zinc, 0.0422, and a trace f antimony. He remarks that it may happen that the ismuth accumulates at certain parts and may exhibit self in certain shapes in the sheet rolled or cast, the actured surface of which is sometimes covered with black coating, or the bismuth-lead alloy may exude rom the metal in fluid condition. Further investiga-on in this direction would probably lead to interesting esults.

Effect of Dirt and Oxide on Lead

It is well known that the presence of dirt and oxide f lead skimmings is responsible in many cases for the reakdown of sheet lead. Oxygen in lead may be re-ponsible for many failures, but Lunge and Schmidt, ho investigated this, concluded that the percentage of xygen in lead is very slight even in extreme cases and oes not seem to have any connection with its liability be acted on by acid. By a special method of analysis evised by them, they found that ordinary soft lead ontains an average of 0.0024 per cent of oxygen. They ade numerous attempts to increase the quantity of xygen artificially but never got beyond a maximum of 005 per cent. As this slight difference in percentage not connected with a perceptible difference in the action of sulphuric acid, the oxygen hypothesis, they say, must be abandoned.

It is presumed that by their reference to oxygen in lead they mean the compound of oxygen and lead. Metallic lead when red hot is capable of dissolving a very considerable quantity of oxide of lead, especially when melted under litharge. In this way at least 1 per cent of oxide, which contains ten times as much oxygen as was found by Lunge and Schmidt, may be introduced into lead. On slow cooling the whole of the dissolved oxide apparently separates and rises to the surface. When the cooling is rapid the oxide has not time to separate and is interpersed throughout the mass, but quite unalloyed with the lead. On hammering a small block of lead treated in this way, it shows innumerable cracks wherever the oxide has separated. If rolled it results in laminations of lead separated by films of litharge, in extreme cases so thick that it drops out when the lead is handled. Sheet lead and pipes have at times more of this entrapped oxide of lead than might be expected and there can be little doubt that to it is due the difference in the behavior of sheets rolled from the same brand of lead.

Process of Rolling Sheet Lead

In making sheets, the pigs of lead are loaded into a large cast-iron melting pot which is provided with a spout at the bottom for running off the melted lead. After the lead is melted and skimmed it is run into a mold placed at a lower level and forms a large block from 6 to 9 in. thick weighing 10 tons upwards. When cold enough it is lifted by means of a crane and transferred to the rolling mill. The rolls are slightly cambered and during the rolling the lead increases very slightly in width and elongates only in the direction of its length. After the block has been reduced considerably in thickness by the rolls it is cut into short lengths, the width of the rolls, and it is then usual to run each length through the rolls at right angles to the previous direction. When the sheet has become so much elongated that it is too long for the rolling table, it is doubled over and the rolling continued, a little chalk having been placed between the sheets to prevent them from adhering to one another. Finally the rough edges are cut off and the sheet is trimmed to the required size and made into rolls for the market.

When the lead is melted a considerable amount of granular scum, composed partly of dirt but mostly of oxide of lead, rises to the surface. Molten lead, like mercury, is very difficult to clean and by continued stirring it is always possible to bring a little more scum to the surface. In practice the lead is skimmed only once and occasionally a small lump of oxide, which may either have been adhering to the side of the pot, or trapped in the spout, passes into the mold and remains below the surface of the lead. Pieces of sheet lead that have failed from this cause are sometimes found with channels and streaks eaten away at right angles to one another when transverse rolling of the piece of lead has taken place. This has been proved by immersing a small lump of oxide in the middle of a block of lead. After rolling into a sheet and submitting to the action of acid for some time, a long channel was eaten away, similar to those which are commonly met with after the thin film of the metal which covered it has dissolved or worn away.

After the lead has been tapped from the melting pot into the mold it cools gradually or, if it is required

[2] *J. Soc. Chem. Ind.*, 1907, p. 504.

at once, the cooling is hastened by pouring water on it. The lead shrinks away from the mold and in the center it sinks, forming a large hollow in which usually the surface of the lead is continuous or unbroken. There are occasions, however, on which the lead has solidified too rapidly on the surface away from the center and in this case there will be found a mass of disrupted crystals in the hollow which penetrate the lead to a considerable depth. These crystals instantly acquire a film of suboxide. A freshly cut surface of lead welds together very thoroughly with pressure, but with the slightest oxidation film welding is impossible. When a sheet is rolled from a block such as this, there will be found in it a large part that will give unsatisfactory results in practice and especially if the sheet is subjected to vibration it will soon exhibit weakness.

Other Causes of Failure

Apart from the presence of impurities probably the chief cause of failure of sheet lead and pipes is due to admixture of oxide of lead, as previously mentioned. The lead in the melting pot is frequently made red hot and the surface of the lead then oxidizes with extreme rapidity and acquires a thick layer of flaky oxide of lead, which is dissolved by the lead near the surface. This lead saturated with oxide finds its way into the mold when sufficient time has not been allowed at a lower temperature for its separation. Although the lead in the mold crystallizes out free from the dissolved oxide, each crystal group is enveloped in oxide of lead. On rolling, these crystals cohere very imperfectly and give rise to the brittleness of the lead which is sometimes noticed in the lead boxes that are made to contain sulphuric acid for export. The small quantity of hydrogen evolved by the action of the acid on the lead gives sufficient pressure to form numerous cracks and the lead becomes so brittle that a slight blow causes it to break. The oxide is often observed when the sheet lead is scraped or cut by a sharp knife.

Failures of sheet lead sometimes occur for which the quality of the lead is not responsible, such as when lead is in contact with mortar, or when the sheets are subject to the vapors of acetic acid and carbonic acid gas. This latter condition sometimes exists when sheet lead is used on the roofs of bonded stores or distilleries. The lead in this case is gradually converted into white lead, as all the elements for the formation of the latter are present. There are numerous other isolated cases, some of which are easy to explain while in others only time and more data will afford a solution.

Chemical Specification for Cast-Iron Pipe

Although there has never been a general agreement between manufacturers' and users' associations on the correct chemical analysis of cast-iron pipe, discussions at a recent meeting of the American Water Works Association foreshadowed an agreement on sulphur limit at 0.10 or 0.12 per cent. At this meeting F. A. McInnes read an interesting paper on causes of failure, in which he remarked that analyses of metal from some of the pipe in the Boston waterworks that has been found broken or cracked during the past 20 years show some "horrible examples." Omitting extremes, the remaining analyses, particularly those in which the sulphur is abnormally high, warrant the conclusion that the quality of the iron was a contributing if not a direct factor in the failure of the pipe.

Cohesion

Rigidity is the outstanding characteristic of a solid, according to Sir George Beilby[1]. "During the past 20 years enormous strides have been made in the study of the ultimate structure of the atom, and in particular the experimental study of the disintegration of the radioactive elements has thrown an entirely new light on interatomic energy. This energy is now known to be of so high an order compared with the molecular forces previously known that many physicists have come to regard these latter as merely residual effects of the interatomic energy. However true this may be, the fact remains that in matter as we know it and as it affects our daily lives, cohesive force must always remain its most fundamental endowment." He describes experiments showing that filings of all metals, when small enough, adhere to each other or to flat surfaces with sufficient force to overcome gravitational attraction. Particles of zinc 0.033 mm. diameter and less will stick to the under side of a plate glass; of gold, 0.133 mm., silver 0.165 mm. and copper 0.099 mm.

"All the experimental researches on the properties of matter at low temperatures go to show that while the qualities of extension and mass which are common to matter in all its forms are unaltered by the removal of heat, the outstanding characteristic of the solid state, rigidity, becomes more and more pronounced as the absolute zero of temperature is approached. In other words, the physical properties which depend on cohesion show by their steady development as the absolute zero is approached that in a heatless universe cohesion would hold undisputed sway. In this universe the diverse properties of the majority of the elements as we know them would be entirely latent; the radioactive elements alone would continue by their disintegration to pass the product of their interatomic energy into a universe in which it would be dissipated and disappear entirely.

"With the advent of heat the all-powerful grip of cohesion is relaxed and the latent potentialities of matter begin to unfold. The waves of ether-borne energy, as they stir the responsive vibrations of the molecules, are to dead matter as the first breath of approaching spring is to the sleeping buds. As among the trees of the forest the response is more ready in some than in others, so among the elements, the lighter and more easily energized, like hydrogen and helium, are already far on in their development toward the ideal freedom of the gaseous state before the less responsive, like platinum and carbon, show any signs of stirring from their lethargy. In the more slowly energized elements we can study the earlier steps in this development, and I think we are now entitled to say that one of the first of these is the acquirement by the molecules of the power of automatic crystalline arrangement."

Fertilizer Used on Cotton

The Department of Agriculture has estimated that commercial fertilizer was used on almost exactly one third of this year's cotton acreage, or on about 11,500,000 acres. On the average 249 lb. of fertilizer was applied per acre and the total fertilizer used was about 1,429,000 tons. This had a total value of $42,121,000, or $29.48 per ton. This was equivalent to a cost of $3.69 for each acre on which fertilizer was used.

New Vessel for the Absorption of Hydrochloric Acid*

A Discussion of the Principles Underlying the Absorption of Gases — The Presentation of a New Absorber and the Illustration of Its Use in Hydrochloric Acid Production

By Stephen L. Tyler
Chemical Engineer, The Thermal Syndicate, Ltd.

THE absorption of hydrochloric acid gas in water at first sight seems to be a very simple proposition. The gas is highly soluble in water and it uld seem that simply bringing together the gas and e absorbent would readily result in complete absorpn.

The problem, however, is not quite as simple as it uld first appear. The solution of hydrochloric acid s in water is one which is highly exothermic and e solubility of the gas is inversely proportional to the mperature. As an example of this, it is possible at a mperature of 0 deg. C. to dissolve over 500 volnes of the gas in one volume of water, while at a temrature of 60 deg. C. less than 350 volumes of gas can dissolved in one volume of water and at a temperare of 110 deg. C. only about 160 volumes may be tained by one volume of water.

Conditions Favoring Absorption

The solution of hydrochloric acid gas in water is pendent upon the following conditions:

1. The temperature of the gas and the liquid.
2. The concentration of the gas in the gases to be scrubbed and the concentration of the acid liquid to be produced.
3. The time of contact between the gas and the liquid; the average distance between the gaseous particles and the liquid particles; the thickness of the liquid layer and its movement internal and as a whole.

Three general methods suggest themselves for bring- about intimate contact between gas and absorbing uid:

1. Spraying the liquid into the gas.
2. Bubbling the gas through the liquid.
3. Contact between liquid and gas by a distribution of the liquid over relatively large surfaces.

The first method mentioned above is not practical efficient in the case of hydrochloric acid because the high heat of solution and the difficulty of remov- the heat generated. By this first method only acid low strength can be obtained. The second method, ile reasonably satisfactory from the standpoint of ducing acid of good strength, is impractical from the chanical standpoint when the apparatus is designed the removal of heat because of the highly corrosive ure of the gas to be handled and the pressure encoun- ed. Thus we have left only the third method or the ect exposure of the liquid to the gas for the satisfactory production of a high strength hydrochloric acid.

Two Methods in Use at Present

At the present time two general methods are used bringing about this intimate contact between the soluble gas and the absorbing liquid. One of these methods employs stoneware vessels (tourills) so designed that a relatively large surface of liquid is exposed to the gas. These vessels are also designed for cooling. The second method uses the vertical tower with a suitable packing material over which the absorbing liquid is passed, thus exposing extremely large surfaces of absorbing liquid to the gas. This latter method is used extensively where gas concentrations are low.

The tourill type of plant is satisfactory for the production of the higher strengths of acid and the design of the apparatus is such as to allow of satisfactory cooling and surface exposure of the absorbing liquid to the gases. There is, however, the objection that this plant requires much floor space and necessitates many connections to maintain a circulation of both liquid and gas. The tower has been used extentively for the absorption of hydrochloric acid gas, but from this it is possible to produce only acids of low strength, as it is not practical to construct absorption towers with sufficient cooling to keep the tower temperature down to a point where high strength acid may be produced.

Principles Involved in the New Absorber

A new type of absorption vessel has recently been developed. The general design of this vessel is shown in Fig. 1. It will be seen that the vessel follows the general design of the S-bend, but has broadened body (3), which is flattened so as to give large surface with relatively small volume. There is a dam or weir (4) at one end of the lower surface which retains a certain quantity of liquid in the bottom of the vessel, thus making this a small reservoir. By following the S-bend principle, the pieces would be set up vertically one above the other, the socket (2) receiving the spigot (1) of the vessel following, thus making an absorption system which amounts to practically nothing more than a single conduit through which both the gases and liquid pass and which has pockets or reservoirs to retain a certain amount of the liquid. Thus the third method of bringing about the intimate contact between the gas and the absorbing liquid is used, but all of the

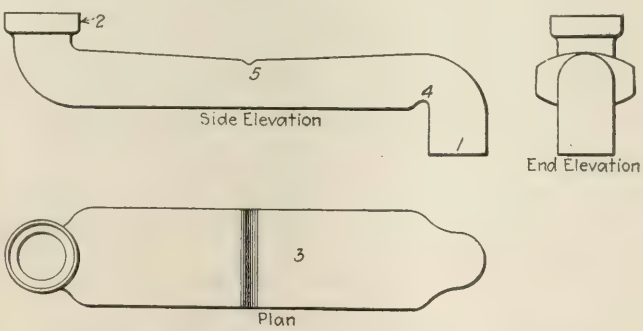

FIG. 1—GENERAL DESIGN OF ABSORPTION VESSEL

*Paper presented before the American Institute of Chemical ineers at Niagara Falls, Canada, June 21, 1922.

objections to the other types of apparatus have been removed by the elimination of small tube connections for maintaining the circulation of the absorbing liquid. These connections have been made generally of glass with rubber as the packing material and have been a very objectionable point, especially because of the fact that they were located necessarily below the level of the absorbing liquid and a leak was certain if breakage occurred or the packing deteriorated.

At the central portion of the roof of the vessel there is a low point (5) toward which the vessel slopes from either end. This sloping of the roof will deflect the gases downward upon the absorbing liquid and bring about very intimate contact. There will be a certain amount of liquid condensed out from the gases as well as some of the liquid run over from the absorption vessel immediately above, which will drip off at this point, making substantially a liquid curtain through which all of the gas must pass. This dropping of liquid on to the absorbing surface has the added advantage that it brings about a complete agitation of the absorbent and thus materially increases the absorption. In absorbing soluble gases in liquids, agitation of the absorbent will always increase the efficiency. There is

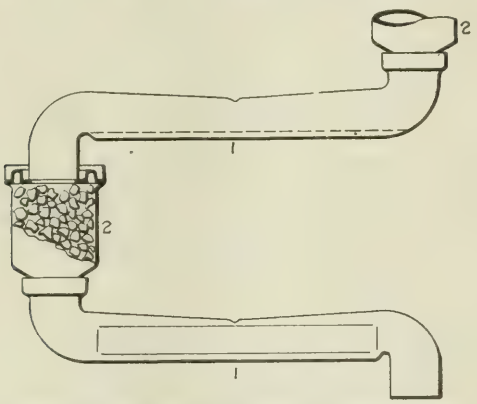

FIG. 2—APPARATUS WITH SMALL ABSORPTION TOWER INSERTED FOR LOW CONCENTRATION OF GAS

also further agitation when the absorbent flows from one vessel to the other, as there is a vertical drop of several inches.

With gases of higher concentration, surface exposure alone is better adapted for their absorption. Therefore the type of vessel just described, if used alone, is more suited to such gases as are generated from the pan side of a "salt-sulphuric" hydrochloric acid plant. In cases where the hydrochloric acid gas concentration is low the same type of absorption vessel may be set up in much the same manner but with interposed packed towers of larger section than the pipe connections themselves.

Modification of New Apparatus for Low Concentration Gas

A set-up showing these short towers is shown in Fig. 2. The packed tower (2) is placed between two absorption vessels (1). The objections already raised to the tower method of absorption in that it does not allow of the removal of the heat generated is overcome in this method of employing towers. The absorbent is thoroughly cooled in its travel through the intermediate absorption vessels.

Suggested Absorption System for Pan Gases

Fig. 3 shows a typical cooling and absorption system for hydrochloric acid produced from the gas generated

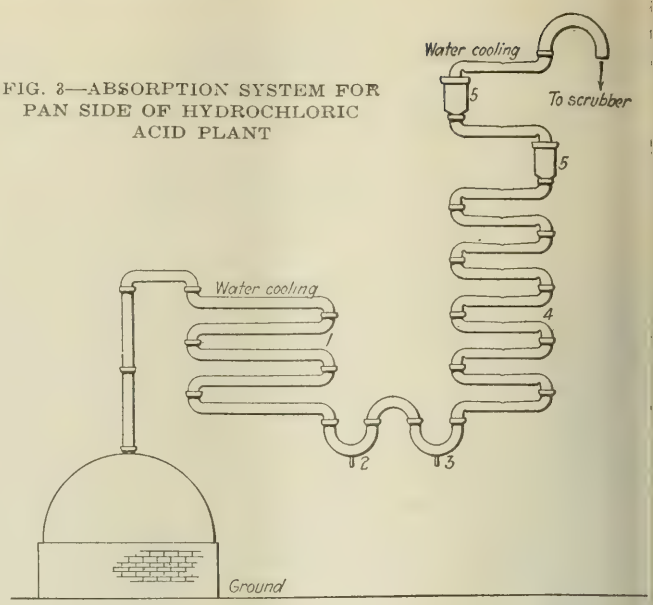

FIG. 3—ABSORPTION SYSTEM FOR PAN SIDE OF HYDROCHLORIC ACID PLANT

on the pan side of the pan and roaster type of plant. It will be noted that the gas first passes through a water-cooled condenser (1) which will remove much of the condensable vapors and lower the temperature of the gas. The condensate produced in this line runs off from a trap (2). The gas passes on through a second trap (3) and up into the absorption system (4). The absorption system operates on the reflux principle so that the strongest gas is in contact with the strongest acid. In the upper portion of this, where the gas concentrations are much lower, towers (5) are interposed between the absorption vessels so as to remove as much as possible of the soluble gas. The gases passing on through this upper portion of the absorption system are carried over to the final scrubbers. The acid produced in the absorption system is taken off from trap (3). The entire absorption system would be thoroughly water-cooled to prevent a rise in tempera

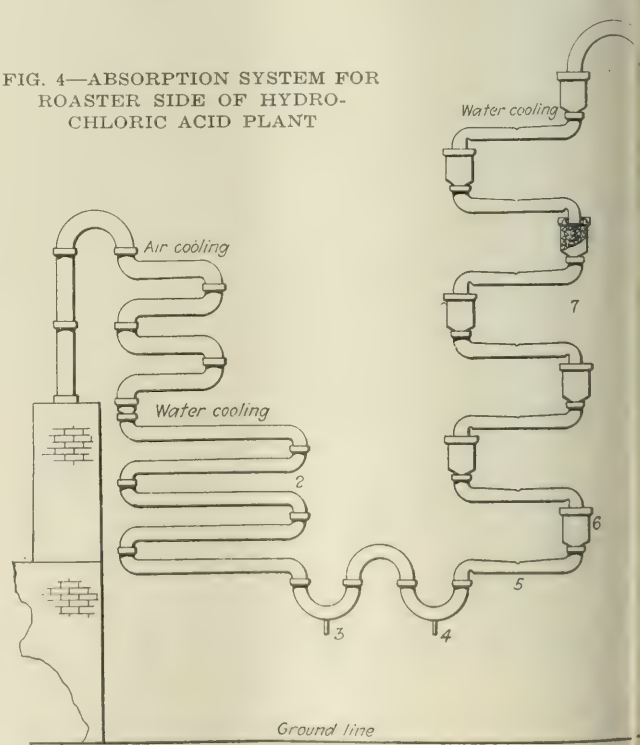

FIG. 4—ABSORPTION SYSTEM FOR ROASTER SIDE OF HYDROCHLORIC ACID PLANT

ture due to the absorption and to insure the production of acid of good strength.

System Modified for Absorption of Muffle Gases

Fig. 4 shows the general design of a cooling and absorption system for the hydrochloric acid gas produced on the roaster or muffle side of the plant. The gases leaving the muffle are first conducted through a series of S-bends (1) which are air-cooled only; then through a second series of S-bends which are water-cooled (2). In this latter set of condensers, the condensable vapors are removed and the gas is cooled. The condensate from both of these coolers is carried off through the trap (3). The gases pass forward through another trap piece (4) and up through the absorption system (7) which is composed entirely of absorption vessels (5) with intermediate towers (6). The exit gases from this absorption train are carried over to a scrubbing system which may consist of another absorption system similar to the one shown or may be a stoneware tower, depending considerably upon the ultimate use for the acid produced.

The type of hydrochloric acid absorption equipment with which this paper deals is designed to be made of fused silica. For such work as this, fused silica is especially well adapted inasmuch as it is insoluble in the acid and thus the product cannot be contaminated. The wall thickness of pieces made up of fused silica is much less than that obtained in any other ceramic material, thus tending toward increasing the efficiency of the cooling and consequently reducing the size of the plant. Such equipment is relatively light in weight so that light supports are ample.

Summary

In summing up the points brought out regarding the type of absorption equipment described, the following points are worth notice: Light weight; economy of floor space; complete agitation of absorbent; liquid curtain through which gas must pass; no joints below liquid level; no glass tube connections or rubber joints; thorough cooling of gas and liquid; intermediate towers give all advantages of tower absorption with none of the disadvantages; complete distribution of cooling water over large cooling surface.

Other uses for the absorption vessel are apparent but the following are possibly worth mentioning:

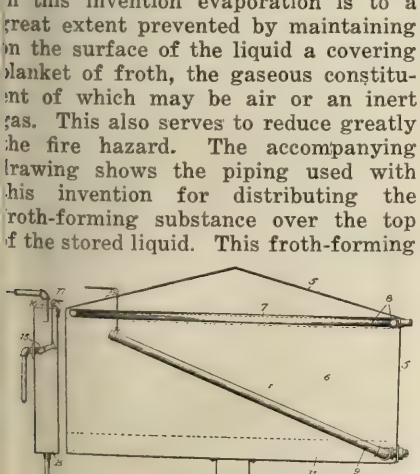
1. As absorber for soluble gases other than hydrochloric acid.
2. For bringing about reactions of gases upon solutions, emulsions or suspensions. An example of this would be some of the chlorination reactions. In this sort of work, the use of the intermediate tower should considerably increase the efficiency of the plant.
3. For the concentration of volatile liquids of boiling points approximately that of water.
4. For fractional distillation of liquid mixtures.
5. As condenser for such vapors as nitric acid where surface exposure to the hotter gases is desirable to insure uniformity of product. The large surface exposure as well as the intimate contact between the hotter still gases and the condensate produced when operating on the reflux principle would give an acid of very good quality and color.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Prevention of Evaporation of Stored Liquids.—Petroleum oils and other similar volatiles are often held in storage for considerable periods of time. The invention covered by this patent aims to prevent evaporation from oils and other similar liquids when so stored. In this invention evaporation is to a great extent prevented by maintaining on the surface of the liquid a covering blanket of froth, the gaseous constituent of which may be air or an inert gas. This also serves to reduce greatly the fire hazard. The accompanying drawing shows the piping used with this invention for distributing the froth-forming substance over the top of the stored liquid. This froth-forming substance can be obtained by dissolving a suitable amount of animal gelatine in water together with a small percentage of a soluble preservative agent as mercuric chloride. (1,415,351; Frank A. Howard, C. I. Robinson and James M. Jennings, assignors to Standard Oil Co. of N. J. May 9, 1922.)



Fertilizer and Process of Making Same.—Graham Edgar of Washington, D. C., has developed an improvement in fertilizer manufacture and assigned it to the government. It relates to the use of calcium cyanamide and tricalcium phosphate in the production of fertilizer containing both fixed nitrogen and phosphoric acid in available forms. It could not be done previously because calcium cyanamide is not effectively converted into urea when treated with acids in the presence of diluents and neutralizing substances such as calcium phosphates, except when the ratio is about 10 to 1. Also because the effective conversion of calcium cyanamide into urea in the presence of acid phosphates occurs only at temperatures of 70 or 80 deg. C. Under these conditions a considerable loss of available phosphoric acid occurs due to the transformation into soluble phosphates. This has limited the amount of calcium cyanamide used in fertilizer mixtures to about 6 per cent. Mr. Edgar's process develops the fact that it is necessary first to treat the calcium cyanamide with strong mineral acids in an amount substantially in excess of that necessary to neutralize the lime content and to maintain a substantial excess of mineral acid throughout the reaction and finally to allow the process to come to completion before adding such diluents and neutralizing substances as bone meal, phosphate rock and potassium carbonate. Urea is very much less decomposed in the presence of strong mineral acids than in the presence of diluents or weekly acidic substances, and therefore higher temperatures may be employed for the reaction as carried out above.

After the reaction has been completed, phosphate rock sufficient to neutralize the excess acid is added. By this process it is possible to produce from calcium cyanamide a fertilizer containing 50 per cent of the total nitrogen in the form of urea and in addition to raise the ratio of urea to phosphoric acid anhydride to one part of urea to three parts of phosphoric anhydride, and may even exceed this, reaching a point where the urea will exceed the amount of phosphoric anhydride present. (1,413,013; April 18, 1922.)

Varnish Composition. — A varnish composition for use as a solvent oil may be prepared from a mixture including approximately 50 per cent by weight of pure vegetable gum, tung oil and thinners, ½ per cent of pure camphor gum, ½ per cent of lavender oil and 49 per cent of naphtha. (1,413,628; H. W. and R. W. Summers, assignors to Detroit Universal Solvent Co.; April 25, 1922.)

Chemical Foundation Defended in Senate

Underwood Upholds Motives and Conduct of Garvan's Organization—Decision Against Foundation Might Be Taken as Precedent and Result in Loss of Other Benefits to Industry

INFORMATION reaching Washington indicates that the chemists and chemical industries of the country have been stirred deeply by the action taken against the Chemical Foundation. The anxiety is not confined to those interested in the chemical industries, as it is feared that Americans may lose the advantages which came with the sale of other alien property.

Another week has passed without any information having been brought out which would cause any of the chemists to desert the Foundation. At the office of the Alien Property Custodian it is stated that the suit will be filed during the first week of August.

Under ordinary circumstances there would be no objection to the suit. It is realized that there are certain legal questions which must be settled, but there is objection to the apparent timing of the action so as to influence legislation. The situation is made worse in the eyes of chemists because it seems to be one of a succession of acts by the Administration which have hurt the chemical industry during the critical period in which it has been endeavoring to establish itself on a scale commensurate with the commercial importance of the country. Several arbitrary acts have been aimed at the Chemical Warfare Service. The State Department suddenly severed its relations with the Textile Alliance. The patent convention was renewed without the adoption of the safeguards which the chemical industry advocated. Then came the action against the Foundation. All of this, combined with the prospects for the defeat of the dye embargo, make the future of the American chemical industry exceedingly dark.

Underwood Defends Foundation

During an extended discussion of the Chemical Foundation matter in the Senate, the only defense of the Administration's course was that a suit against the Foundation is necessary in order to meet the suit which the Foundation brought to establish the status of the royalties paid into the U. S. Treasury. Senator Underwood spoke effectively in defense of the Foundation. It is probable that a further defense of the Foundation will be made in the near future on the floor of the Senate, by a prominent Republican member.

Senator Underwood prefaced his remarks with the explanation that it is advisable at this time to review the facts surrounding the matter. Before he had proceeded far in his speech he was upbraided by Senator Nelson of Minnesota, chairman of the Committee on the Judiciary, for making an elaborate argument in behalf of the sale of the German patents to the Chemical Foundation. "I am astonished," he said, "that the conservative Senator from Alabama should take a case of this kind out of the hands of the courts and attempt to try it in the Senate."

To this Senator Underwood retorted: "The reason why I make this statement is not a question of trying to interfere with the courts, but I know that this attack is coming from the German lawyers in this country who are trying to get back the property of their clients." He declared that it is a mistake for the government to take this action against the Chemical Foundation. If the government succeeds in having set aside the transfer of these chemical patents to the agency created for the benefit of the American people, what is to become of the patents, he demanded. "Are you going to give them back to Germany or where do they go?" asked the Senator. "If you give those chemical patents back to Germany they go to the German cartel, a trust in Germany."

No Fraud Apparent

Senator Underwood traced the history of the legislation under which alien property was seized. He pointed out that the Germans had taken out these patents for the purpose of stifling industry in America. "The spirit of our patent laws," he declared, "had been violated, and our hospitality abused when the Germans took out those patents here for the sole purpose of building up in Germany the great industrial and war machine with which they expected to subdue the world."

The fact that A. Mitchell Palmer submitted his entire plan for the sale of the patents to the Chemical Foundation to Congress 2 months before the action was taken is evidence, Senator Underwood declared, that there could have been no fraud intended.

"This report effectually disposes of the charge that there was a fraudulent conspiracy on the part of those in the Alien Property Custodian's office," continued Senator Underwood. "The charge has been repeatedly made that Mr. Garvan, as Alien Property Custodian, sold these patents to himself as president of the Chemical Foundation. It will be seen, however, from this report which was made before Mr. Garvan became Alien Property Custodian or had any thought of being appointed to that office, that the entire plan was devised and perfected and the sale made while Mr. Palmer was in office.

"It was Mr. Garvan's announced purpose then to resign his subordinate place in the Alien Property Custodian office and take the presidency of the Chemical Foundation without salary or compensation for expenses, but on March 4, 1919, Mr. Palmer was appointed Attorney-General, and President Wilson, with full knowledge of the entire Chemical Foundation matter made Mr. Garvan Alien Property Custodian. It is true that the actual assignment of the patents to the Chemical Foundation was not ready until April 10, 1919, and it was signed by Mr. Garvan as Alien Property Custodian, but as shown by Mr. Palmer's report, the entire matter had been concluded and consummated before Mr. Palmer went out of office, and the signing of the papers was a mere formality.

Aim to Prevent Monopoly

"Conspiracies to defraud are not committed in the open light of day. Conspiracies to defraud the government are never reported to Congress by the conspirators in advance. How could a

(Continued on page 229)

Senate Committee Splits on Muscle Shoals

As had been expected, the Senate Committee on Agriculture split in much the same manner over the Muscle Shoals proposition as did the Committee on Miltary Affairs of the House of Representatives. The Senate committee, like the House committee, was almost evenly divided for and against the acceptance of the Ford offer.

The situation differs from that in the House committee in that Chairman Norris, joined by Senators McNary of Oregon, Norbeck of South Dakota, McKinley of Illinois and Gooding of Idaho, recommends the incorporation of the Federal Chemical Corporation to operate the Muscle Shoals property for government account.

Senator Kendrick, of Wyoming, explained to the Senate that his only objection to the Ford offer is the fact that the lease period is for 100 years. He believes no lease of waterpower should exceed fifty years, the limit prescribed by the waterpower act.

American Ceramic Society to Visit Canadian Plants

lembers Will Be Busy for Week Inspecting the Numerous Industries of the Dominion

Detailed plans for the Canadian sumer meeting of the American Ceramic ociety emphasize the fact that the eek of Aug. 13 to 19 will offer unsual opportunities for the inspection a variety of ceramic plants under ost enjoyable circumstances.

The party will leave Rochester Sunay, Aug. 13, at 9:45 p.m. standard me, on the steamer Kingston, arrivg in Montreal Monday at 6:45 p.m.

INSPECTION TRIPS

Tuesday, Aug. 15, will be spent in ontreal. G. Percy Cole, of the Dominn Glass Co., will be in charge of the sits to Montreal Pottery; Trenton otteries; Dominion Glass Co.; Point . Charles Works (bottles on Owens achine); Delorimiert Works (punch mblers, chimneys, etc.); McGill Uniersity; Consumers Glass Co. (semiutomatic machine on bottles and mblers); Nation Brick Co. Ltd.; aprairie Works and Delson Junction orks; Thomas Davidson Manufacturg Co., Ltd. (enameled ware); Gurney oundry Co., Ville St. Laurent (stove ameling, three furnaces), and the nada Cement Company, Ltd.

Wednesday, Aug. 16, will be spent in uckingham, Ont., with N. B. Davis in arge. On arrival at Buckingham, at :20 a.m. the excursion will proceed motor to the Derry feldspar quares. This 10-mile drive is through one the most beautiful sections along the evre River. The return trip will be ade in time to leave Buckingham at p.m. for Ottawa.

A brief but crowded trip to Ottawa Thursday will be under a committee mposed of N. B. Davis, Howells echette, Joseph Keele and D. Merkley. lternative excursions have been arnged to the Parliament Buildings; ctoria National Museum; Ceramic aboratories, Department of Mines; per mills and Merkley's brick plant.

VERONA, KINGSTON AND TORONTO

The party will leave Ottawa at 10:40 n. arriving at Verona at 2:34 p.m. ere R. F. Segsworth and Everett wnsend will be in charge and the rty will be conveyed from Verona to e famous feldspar quarries of this strict. A real camp dinner, cooked d served by camp cooks, is to be joyed in the Verona wilds.

The party will leave Verona at 6:35 n. for Kingston, arriving at 7:35 p.m. ter a banquet by Kingston Council d a visit to the Frontenac Floor & ile Tile Co. the visitors will leave in ecial Pullman sleeper for Toronto, ere they will spend Friday.

The day in Toronto is being arranged M. F. Gibson, A. N. Cote and R. K. bertson. Their plans include visits Standard Sanitary Works; Dominn Glass Co.; Jefferson Glass Co.; eral brick and tile companies; Toronto University and Queens Museum. Friday night will be spent in Toronto, the party leaving the next morning for Hamilton, where visits will be made to the Dominion Glass Co.; Canadian Libbey-Owens Sheet Glass Co.; General Porcelain Co.; National Fire Proofing Co. and Canadian-Harts Products Co.

Business Library to Be Selected by Industrial Leaders

Two thousand business men, one hundred national leaders in each of twenty basic industries, are selecting a representative business library to be placed in the Hotel McAlpin, New York, and to include the ten most authoritative books on every branch of business and industry.

Bank presidents, railroad heads, insurance presidents, advertising executives, textile manufacturers, wholesale grocers, department store heads and engineers are helping L. M. Boomer, managing director of the hotel, to collect this library. The bibliography will be made available to chambers of commerce and other business organizations.

The library when completed will comprise the ten most authoritative books covering the fields of Insurance, Banking, Textiles, Groceries, Railroads, Shipping, Automobiles, Iron and Steel, Coal, Lumber, Grain, Rubber, Shoe and Leather, Department Stores, Clothing, Advertising, Printing, Paper, Accountancy, Credit, Sales Management, Publishing, Foreign Trade, Building, Heating and Ventilating and Furniture.

The method of selection is to analyze the lists received from the one hundred leaders in each industry and thus select the books which are mentioned the greatest number of times. The ten books in each field most often selected will be those included in the library. The lists will be re-submitted to a committee of experts for further voting if there is not sufficient unanimity of opinion.

I. C. C. Ruling on Cyanamid—Sulphur Rates Protested

Deciding the complaint of the American Cyanamid Co., the Interstate Commerce Commission hold that the rates on cyanamid from Suspension Bridge, N. Y., and Niagara Falls, Ontario, Canada, to San Francisco, Los Angeles and other Pacific coast destinations in California are unreasonable. It prescribes reeasonable factors beyond St. Louis not exceeding 81.5 cents per 100 pounds and effective Sept. 6.

The Texas Gulf Sulphur Co., has entered a complaint against the rates on sulphur from Jersey City, N. J., to Baltimore, Md., and from Baltimore to Brills, N. J., on the ground that the present rates are unreasonable.

Unreasonable rates on sulphuric acid from Grasselli and Brill to Seaboard, N. J. are alleged by the Seaboard Byproduct Coke Co. of Pittsburgh. The General Chemical Co., of New York, complains against unreasonable rates on sulphuric acid from Undercliff to Maywood, N. J.

Trade Board Drops Resale Price Cases

Forty Old Complaints Quashed Since Supreme Court Has Found Practice Illegal

The Federal Trade Commission has dismissed, without prejudice to its right to institute new proceedings, about forty complaints against as many nationally known business concerns which it had charged with maintaining resale prices similar to those in what was known as the Beech-Nut Packing case.

These cases involve resale price maintenance and were suspended by the Commission to await the determination of the Beech-Nut Packing case, which case was selected and advanced by the Commission as a test case. In the Beech-Nut case the Supreme Court upheld the position of the Commission with respect to resale price maintenance.

After the Beech-Nut decision the Commission considered its suspense calendar and concluded, in view of the Beech-Nut decision and the age of the cases on suspense, that the cases suspended should be dismissed without prejudice, as it appeared to the Commission that the Supreme Court had settled the law with respect to price maintenance, and to bring these forty cases to a conclusion would involve a large expenditure of time and money and would require the amendment of the complaints to bring them down to date, and rather than amend its complaints, which would require reinvestigation, the Commission dismissed them without prejudice.

At the same time the Commission instructed its chief examiner to institute a new inquiry with respect to each of the dismissed cases and if it appeared that violations of law were found to exist within the meaning of the Beech-Nut decision, to report the facts to the Commission for determination as to whether or not new complaints should issue.

CHEMICAL COMPANIES INCLUDED

The companies against which complaints were dismissed included: The General Chemical Co., American Thermos Bottle Co., De Miracle Chemical Co., Kryptok Sales Co., L. E. Waterman Co., H. L. Hildreth Co., Massachusetts Chocolate Co., Marinello Co. of Wisconsin, Marinello Co. of Illinois, Vortex Manufacturing Co., Curtis and Co. Manufacturing Co. and Curtis Pneumatic Machinery Co., William Waltke & Co., Crescent Manufacturing Co., Goodyear Tire & Rubber Co., The Procter & Gamble Co., The DeLaval Separator Co., Buffalo Specialty Co., American Graphophone Co., Columbia Graphophone Co., The Gates Rubber Co., J. E. Hunt & Co., Pennsylvania Salt Mfg. Co., Colgate & Co., The Sheets Elevator Co., The Vick Chemical Co., Colorado Milling & Elevator Co., United Electric Co., Hillerich & Bradsby Co., Klaxon Co., D. M. Ferry & Co., Tungsten Manufacturing Co. and the Domestic Engineering Co., Inc.

Plans for Chemical Exposition Include Features Which Insure Success

Four Hundred Exhibitors Signed to Date Including Many Novelties and New Features—Society Programs and Motion Pictures Will Add to Activity

WITH over four hundred exhibitors signed up for booths at the Chemical Exposition, the success of the annual "big show" is assured. The Exposition this year will be the eighth held in New York. It has been purposely scheduled to occupy the week between the American Chemical Society meeting in Pittsburgh and that of the American Electrochemical Society in Montreal so that the month of September will be a busy one in chemical circles.

The Exposition will open on Monday, Sept. 11, at the Grand Central Palace, New York, and continue through the entire week. The exhibitors include most of the firms that have taken space in previous years and a number of companies that will exhibit for the first time. To date, five technical societies have definitely scheduled meetings to be held in the auditorium at the Exposition. Motion pictures dealing with varied phases of chemistry and engineering have been arranged for evening exhibition through the week. All in all, the 1922 edition of the Chemical Exposition offers enough of interest to the profession to occupy several days of one's time at the Grand Central Palace.

Exhibits and Exhibitors

Every branch of the chemical and chemical equipment industries will be represented among the exhibitors, as well as numerous allied houses. The chemical products which will be on display will include all varieties manufactured in the United States—coal-tar medicinals and dyestuffs, technical chemicals for the rubber, leather, paper, textile, paint, and other consuming trades. In the apparatus and machinery branches, the exhibits will take in every phase of chemical plant and laboratory equipment.

A number of new devices, developed during the past four years since the termination of war-time activity and completed since the 1921 Exposition, will be displayed for the first time this year. Many improvements on machinery long standard for industrial operations will be shown for the first time. A great many of the machines and instruments will be seen in actual operation. Something new in a special high capacity evaporator lead pump for handling phosphoric acid under pressure, a new adaptation of the hard rubber pump in hydrochloric acid loading, a recent development on a balanced automatic control valve and in a direct reading resistance thermometer, new ideas in pyrometers, developments of the past year in butyl alcohol derivatives for solvent purposes, recent developments in the use of chlorine bleach liquor in the paper industry in place of bleaching powder, new dust controlling and humidifying equipment, new ideas in loading machinery for trucks, new departures in all types of containers, steel, fiber, wood, and glass —new ideas in all branches of the industry will be on display. One of the well-known associations will display a wall chart on which will be listed every manufacturer in the United States of ordinary quicklime with a full chemical and physical description of each brand now on the market.

Several special sections are being planned. One will be given over to photographic materials, supplies and microscopes, in connection with the exhibit of the Technical Photographic and Microscopical Society. Another special section will be devoted to a fuel economy display which will include the products and services of nearly 100 firms. Another section will be given over to exhibits showing fire and dust explosion prevention in mills, industrial plants, grain elevators, mines and factories. This exhibit is being arranged by the Bureau of Chemistry and the Bureau of Mines. There will be shown fire extinguishing apparatus of the most modern kinds. Another novelty will be the container section, showing shipping containers of all kinds and in which packaging, labeling, package handling and shipping machinery will be exhibited.

Society Meetings

It is estimated that 100,000 persons will visit the Exposition this year from all parts of the country. Several of the societies have taken advantage of this congregating by scheduling meetings in connection with the show. Each afternoon the program will be given over to a series of events to be arranged by one of the scientific or business associations of the chemical industry, according to the plans which have been tentatively outlined. The Technical Association of the Pulp and Paper Industry, the Synthetic Organic Chemical Manufacturers Association, the American Ceramic Society, the Salesmen's Association of the American Chemical Industry, and the Technical Photographic and Microscopical Society have arranged to take care of the program for one afternoon each. The standardization program with its numerous different phases will also fill an afternoon session. The evening sessions will be given over exclusively to motion pictures, a number of which will be accompanied by lectures on various developments in the chemical and allied industries. All meetings will be held in a special auditorium in the Grand Central Palace provided for the purpose by the Exposition management.

T. A. P. P. I. Program

The Technical Association of the Pulp and Paper Industry has about completed its program. The Association is introducing a new idea in holding this particular type of meeting

VIEW OF MAIN FLOOR OF CHEMICAL EXPOSITION

The regular technical meetings o T. A. P. P. I. were formerly held eac year in connection with the Expositio but the meeting this year is of a speci nature. It is intended especially as a opportunity for manufacturers equipment applicable to the paper i dustry to describe their products t representatives of the industry and o the other hand, for the operating me to learn of the advantages offered b the latest developments in the equi ment field. Each speaker will prese an idea concerning the product of h company, not with the object of hypn tizing his audience into a buying org

Metz, in Germany, Voices Opposition to Dye Tariff

eclares Former Enemy Plants Can Never Supplant New Industry in the U. S.

Herman A. Metz, head of Metz & ., importers and manufacturers of es and synthetic chemicals, has cabled om Germany a correction of state- ents attributed to him on the dyes riff.

"It is true," said Colonel Metz, "that e are importing only about 10 per cent our dye requirements and it is true at German dye plants as well as other dustrial enterprises based on a dollar lculation are worth only about 10 per nt of their pre-war capital, despite the rge increases of capital stock issued many of them. I was much amused the comments made by a 'prominent ctor.' If these 'prominent factors' and yestuff authorities' only had the nerve put their names to their statements would soon know which of them were id propagandists or publicity agents d which really knew what they were lking about.

Depreciation of Mark Explains Huge Dividends

"Any primary school boy can figure t the present conditions. Before the ar the three largest dye and chemical hey always forget the chemical part) ants had a capital of 54,000,000 gold arks each. That equals about $12,- 0,000 each, for three of the plants ne, as the rest were smaller. To be rth the same amount in dollars (and rtainly buildings, land, plants and ocesses are as good as ever in pro- rtion) each of these three plants, tting the mark at 400 to a dollar, ould have a capital of 5,000,000,000 arks, or 15,000,000,000 for the three rgest. If, in view of the actual fig- es, you can work out a shrinkage in lue of less than 80 or 90 per cent I uld like to see it. And in figuring e 'exorbitant dividends' of 20 or 30 r cent, we must bear in mind that ey also are paid in paper marks, and at where formerly four marks were rth one dollar, now it takes over 400 buy one dollar or one dollar's worth goods, and then you get from one- ird to two-thirds the amount of goods u formerly got for a dollar.

Labor a Small Factor

"Of course labor, even at 30 (or 50 arks an hour, which it may soon be) cheap compared with the United ates. But bear in mind the fact that or is only about 10 per cent of the st of dyes and chemicals, while benzol d the main coal tar derivatives are expensive in Germany as in the ited States and the same are being ught in America, while coal, which w is largely bought in England, since ance takes the German coal, is as h or higher. You get a different nt of the whole situation.

"I have not changed my views one bit and I still insist that we must have a healthy chemical industry in the United States and want sufficient tariff to give it to us; but I want to get it by honest, above-board means and not under false pretences."

Arsenic Tariff Burden Discussed in Senate

Charges that the recent duty of 2 cents per pound on arsenic adopted by the Senate in the revised tariff bill will subject the cotton growers to a tax of $18,000,000 were made in a Senate debate on the cotton schedule by Senator Smith of South Carolina. Senator Robinson, of Arkansas, also opposed the duty on the same score while Senator Smoot, of Utah, for the Finance Committee, denied that the duty would impose such a tax. He said that based on last year's imports the duty would not exceed $100,000.

Chemical Foundation Defended

(*Continued from page* 226)

conspiracy be successfully charged here in view of the fact that the Alien Property Custodian, before the final act which transferred the property, made a full and complete report of his plans and purposes and the reasons therefor to the Congress of the United States, to which wide publicity was given at the time? If the Chemical Foundation had been a strictly private institution for profit, engaged in the manufacture of chemicals, the sale to it for $250,000 would have been properly subject to attack, for it would have given for a trifling consideration a monopoly in the production of chemicals. But it was just to avoid this kind of situation that the Chemical Foundation was formed."

Trustees Control Foundation

The Senator brought out the point that neither Mr. Garvan nor the Foundation stockholders are the real controlling factors in the organization. The names of the men to whom the power is given to vote the stock and to control the corporation are as follows: George L. Ingraham, former Chief Justice of the Appellate Division of the Supreme Court of New York; Otto T. Bannard, president of the New York Trust Co.; Cleveland H. Dodge; Benjamin Griswold, Jr., head of the firm of Alexander Brown & Sons, bankers, of Baltimore, and Ralph Stone, president of the Detroit Trust Co. All of them are men whose character and standing may not be questioned by anybody in the United States. They have the voting power of the stock in their hands as trustees and control in that way the Chemical Foundation for the benefit not of the stockholders, because the stockholders merely made a 6 per cent loan, but they control it in order that there may not be a monopoly created of these patents and that anyone in the United States who is willing to pay a reasonable royalty may use the patents.

Senator Wadsworth, of New York, the chairman of the important Committee on Military Affairs, made the following statement in regard to the Chemical Foundation to the Washington correspondent of *Chemical & Metallurgical Engineering:*

"The motives of Mr. Garvan and of those associated with him in the formation of the Chemical Foundation were good and patriotic. There is no reason for attacking these men. They are sincere and have a most worthy objective in attempting to preserve and to build up a domestic chemical industry without profit or emolument for themselves.

"I have no criticism for the action of the Administration but I am very sorry that, as an incident to this legal action, the motives of the men carrying on this work have been attacked. The Chemical Foundation has performed a very valuable function. I regret the attacks on the character of the Foundation, but it should be allowed without prejudice to establish its legal right to live."

Attempt to Adopt Uniform Standard for Alcohol Determinations

At the last meeting of the Association of Official Agricultural Chemists, criticism was made of the A. O. A. C. and U. S. P. alcohol tables. The sentiment appeared to be in favor of the A. O. A. C. tables. The chairman of the committee to co-operate with the U. S. Pharmacopœial committee of revision, appointed at the last meeting, has discussed the question considerably with the conviction that a conclusion is not so easily arrived at. The committee itself is divided; two are in favor of the A. O. A. C. alcohol tables and two in favor of the U. S. P. alcohol tables.

In view of the unsatisfactory outcome so far, the chairman is submitting the matter to the A. O. A. C. membership for discussion, criticism and a vote.

It is conceded that the most convenient temperature for making routine observations is the laboratory temperature, but this temperature varies considerably from time to time and in different sections of the country. The A. O. A. C. tables are based on the Bureau of Standards table 20 deg./4 deg. and represent true specific gravities, whereas the U. S. P. tables are based on the Bureau of Standards tables 15.56 deg./15.56 deg., and are apparent specific gravities, barometer at 760 mm. with 50 per cent air saturation. The Bureau of Standards has not committed itself to any temperatures for alcohol tables or for determining specific gravities of alcoholic mixtures. The Standards Bureau has adopted 20 deg. as the temperature for standardizing apparatus. 20 deg./4 deg. is considered the more scientific, but 15.56 deg. is more largely used in the industries and by industrial chemists and 60 deg. F./60 deg. F. is written into the internal revenue law dealing with alcohol products. The Gauger's Manual tables are also based on this temperature.

Mining Engineers Honored by French Government

A. S. Dwight and C. F. Rand Decorated for Distinguished Services to Their Country and Profession

For distinguished service during the war, Col. Arthur S. Dwight, president of the American Institute of Mining and Metallurgical Engineers, and Charles F. Rand, chairman of the Engineering Foundation, were decorated with the Croix de Chevalier de la Legion d'Honneur by the French Government on July 20. The decorations were conferred by Consul General Gaston Liebert at a luncheon given in his honor at the Engineers' Club, New York City, and attended by engineering leaders from many parts of the country, including representatives of the national organizations of civil, mining, mechanical and electrical engineers and of the Federated American Engineering Societies.

In presenting the decorations, Consul General Liebert extolled Col. Dwight and Mr. Rand as personifying the spirit and service of the American engineer, which, he asserted, was a powerful factor in the victory over Germany. M. Liebert said that there was a growing friendliness between the United States and France. The two countries, he declared, have come to understand each other better since the Genoa and the Hague Conferences. The general Franco-American situation, he thought, has greatly improved since the Disarmament Conference in Washington.

Col. Dwight and Mr. Rand rank among the leaders of American engineering. Both have previously been honored by foreign governments. Col. Dwight aided in recruiting and training the Eleventh Engineers, the first unit of the A.E.F. in action, thrilling the nation on November 30, 1917, when it went to the assistance of Haig with pick and shovel during the German drive for the Channel ports. Col. Dwight served twenty-two months overseas, receiving the D.S.O. from the British, and being cited by General Pershing. He is a former alumni trustee of Columbia University, where he was graduated from the School of Mines, in 1885.

Mr. Rand is internationally known as the head of large mining properties in this country and Cuba. He discovered the great soft iron ore deposits of the north Cuban coast and has been active in Cuban railroad building. In 1913, Mr. Rand was decorated by King Alfonso of Spain with the Grand Cross of Knight Commander of the Order of Isabella Catolica for distinguished services to Spain and to mining. He is an honorary member of the British Iron and Steel Institute, of which the only other honorary members are the Prince of Wales, the King of the Belgians, Dr. Richard Akerman and Baron Gustaf Tamm. Mr. Rand is a director and past president of the American Institute of Mining and Metallurgical Engineers and as the head of the Engineering Foundation is active in promoting industrial research in America.

Plans for Chemical Exposition

(*Continued from page* 228)

but with the idea of acquainting his auditors with the merits of his product and its proper application so that the latter can judge whether or not they are taking best advantage of the production aids which the equipment manufacturers are devoloping. The program is as follows:

W. C. Edge of Paul B. Huyette Co., "Safety and Efficiency Appliances for the Boiler Plant."

E. J. Trimbey of the Trimbey Machine Works, "Trimbey & Tibbitts Proportioning and Metering System for Paper Stock."

George L. Dickey, Industrial Filtration Corporation, "Rotary Filters for Washing of Paper Pulp and for Filtering and Washing Caustic Lime Mud." (Illustrated.)

H. A. Morrison, Oliver Continuous Filter Co., "Efficiencies and Economies in Washing Black Liquor from Digested Soda and Sulphate Stock."

L. D. Mills, The Merrill Co., "The Merco Nordstrom Plug Valve."

H. S. Thayer, Atlas Electric Devices Co., "Testing Colored Materials for Fastness-to-light."

A. E. Campbell, The Schaeffer & Budenberg Mfg. Co.., "Instruments for Promoting Efficiency in the Paper Mill."

H. G. Bean, The Bristol Co., "Application of Recording Instruments in Pulp and Paper Industry."

C. C. Phelps, Uehling Instrument Co., "The CO_2 Record of Combustion Efficiency."

Harry Carlson, Sandvik Steel, Inc., "Steel Belts and Their Application to the Solution of Conveying Problems."

H. Austin, Ernest Scott & Co., "Scott Evaporator as Used in the Pulp Mill for Recovering Soda from Spent Liquors."

L. G. Chase, Yarnell-Waring Co., "The V-Notch Meter and its Application to the Paper Mill."

W. D. Mount, Glamorgan Pipe & Foundry Co., "Continuous Causticizing with Lime Recovery and Reuse."

Jerome D. Stein, Grinnell Co., "The Grinnell Dryer Applied to Wall-Paper and Coated Paper."

Hoover to Address Salesmen

The Salesmen's Association of the Chemical Industry has announced that Herbert Hoover will address its meeting at the Exposition. Mr. Hoover will talk on "Standardization, and What It Can Do for the American Chemical Industry." Wayne B. Wheeler, general counsel for the Anti-Saloon League and considered one of the foremost authorities in the United States on alcohol and prohibition legislation, and also active in the rigid enforcement of the Volstead act, will also address the assemblage on "The Attitude of the Anti-Saloon League Toward Industrial Alcohol."

Symposium on Standardization

On the "Standardization" program, tentative arrangements have secured the following speakers: W. D. Collins, United States Geological Survey, on "Moderation in Standardization"; N. F. Harriman, United States Bureau of Standards, on "Standardized Testing Apparatus"; I. G. Jennings, Glass Container Association, on "Discussion of the Reasons for the Varieties of Shapes and Sizes"; J. M. Roberts, secretary of the Apparatus Manufacturers' Association of the United States on "What Has Been Accomplished in the Standardization of Scientific Apparatus"; Ross C. Purdy, secretary of the American Ceramic Society and chairman of the committee on refractories of the American Society for Testing Materials, on "Standardization of Fire Clays and Refractories" Emerson P. Poste, Elyria Enameled Products Co., on "Standardization of Enameled Wares for Chemical Purposes." Other details of the program have not as yet been arranged and will be announced later, when the complete list of speakers is assured.

Motion Picture Program

An unusually interesting array of motion pictures will be shown evening at the Exposition. The subjects covered are timely and diversified and it will be impossible to visit the Grand Central Palace in the evening without having opportunity to see a film that will be of interest to technical men in general.

One of the features of the evening programs will be an illustrated address by David Wesson on "The Romance of Cotton."

The complete program of films to be shown follows:

"Recovering Values from Fume and Smoke," by courtesy of the U. S Bureau of Mines and the Research Corporation.

"Inspiration: One of the World's Great Copper Mines," by courtesy of the U. S. Bureau of Mines.

"The Story of Sulphur," by courtesy of the U. S. Bureau of Mines and the Texas Gulf Sulphur Co.

"Mexican Petroleum," by courtesy of the U. S. Bureau of Mines.

"The Story of Heavy Excavating Machinery," by courtesy of the U. S. Bureau of Mines.

"The Story of Abrasives," by courtesy of the U. S. Bureau of Mines and The Carborundum Co.

"The Story of Air Reduction."

"The Story of Natural Gas."

"The Story of Asbestos," by courtesy of Johns-Manville, Inc.

"Fire Fighting with Foamite Firefoam," by courtesy Foamite Firefoam Co.

"The Manufacture of Newsprint Paper at the Spanish River Pulp & Paper Co. Mills in Ontario," by courtesy of the G. H. Mead Co.

"Nickel and Copper Mining, Smelting, and Refining," by courtesy of the International Nickel Co.

"Prospecting for Gold in Northern Ontario" and "Assaying for Gold in Northern Ontario," by courtesy of the Ontario Department of Mines.

Franklin Medal Presented to English Scientist

Sir Joseph J. Thomson, Master of inity College, Cambridge, was pre-nted with the Franklin Medal by the ranklin Institute on July 26, in Lon-n, for his "signal and eminent rvice in science."

The presentation was made by the arl of Balfour, who referred to Sir seph as one of the greatest pioneers an age prolific in marvels and iracles of scientific discoveries and hievements.

In replying, Sir Joseph said he was ad if he had contributed to the otherhood of science between Great ritain and America. He reviewed ranklin's epoch-making achievements. ranklin had attained his position nong the immortals in science by a ief six years of work, and in spite of e fact that he had to the end of his fe no knowledge of mathematics. ranklin was one of the most daring adventurers in speculative science. was his speculative contributions at had proved most valuable.

Those attending the presentation in-uded Dr. Ellwood Hendrick, Consult-g Editor of *Chem. and Met.;* Prof. T. Goodstead of Berkeley, Cal., and rofessor W. G. MacCallum of Balti-ore.

ennessee Coal, Iron and R.R. Co. Announces Expansion

Following closely its announcement the immediate construction of a odern 10- and 12-in. merchant bar ill at Fairfield, the Tennessee Coal, on & R.R. Co. announces that it will mediately construct a steel foundry the plant of the Chickasaw Ship-ilding & Car Co. at Fairfield and re-odel the Ensley foundry. The official nouncement of George Gordon Craw-rd, president of the Tennessee com-ny, follows:

"A modern steel foundry will be con-ructed at the Fairfield works of the ickasaw Shipbuilding & Car Co. and ien this is completed the Tennessee al, Iron & R.R. Co. will remodel the undry at the Ensley works to im-ove facilities for manufacturing in-t molds and iron castings."

Personal

J. M. Cobb, connected with the United ates Bureau of Mines, is directing a urse of first aid instruction for em-oyees at the plant of the American ricultural Chemical Co., Pierce, Fla. ie series of lessons was commenced July 10.

Colonel Arthur S. Dwight, presi-nt of the American Institute of ining and Metallurgical Engineering, d Charles F. Rand, chairman of the gineering Foundation, were deco-ted July 20 with the Croix de Cheva-r de la Legion d'Honneur by the ench Government, for distinguished vice during the war.

J. M. Gillet, formerly in the chemical engineering department of the Goodyear Tire & Rubber Co., is now chemical engineer with the Lamberson Japanning Co., Chicago, Ill.

A. A. Holmes has recently severed his connection with the E. B. Badger & Sons Co. and has been appointed sales manager for the American Trona Corporation, with headquarters in New York City.

Ulric J. Lebourveau of Stamford, Conn., recently resigned from the Atlas Powder Co. after 7 years of continuous service. During the last 5 years he has been connected with the research division on experimental and development work. Mr. Lebourveau has not yet made any definite plans for the future.

Dr. R. B. Moore, chief technologist at the Bureau of Mines, has returned from a business visit to Europe.

Sloan S. Sherrill, formerly plant engineer for the Calumet Chemical Co. of Joliet, Ill., a subsidiary of the Calumet Baking Powder Co. of Chicago, severed his connection with that company to accept a position with the Universal Oil Products Co. of Chicago, as mechanical engineer on its operating staff. Before his connection with the Calumet Chemical Co. he was on the engineering staff of the Chemical Construction Co. of Charlotte, N. C.

Linus S. Sterritt, general manager of the United Paper Board Co., Lockport, N. Y., has resigned, to become manager of the plant of the Eddy Paper Co., Three Rivers, Mich.

Robert T. Stokes, formerly assistant editor of the *Journal of Industrial and Engineering Chemistry,* is now secretary of the Biscuit & Cracker Manufacturers' Association, New York City. He succeeds the late Edward Griswold.

Obituary

T. J. Menten, vice-president of the Schaeffer & Budenberg Co. and the American Steam Gauge Co., died on July 9 after a brief illness. Mr. Menten was prominent for many years in the field of recording instrument manufacturers.

William Benjamin Smith, chemical engineer and inventor, died on July 19 at Washington, D. C. He invented the first grain reaper used in Georgia, and the Smith American car axle journal bearing. He made commercially profitable the use of potash from feldspar for agricultural purposes. He recently completed tests of an insecticide fertilizer which has been used in the South against the boll weevil.

The death, on July 22, of Dr. Jokichi Takamine robbed the chemical industry of one of its most brilliant leaders. But to his native country, Japan, and to his adopted country, the United States, the loss is of even greater significance, for Dr. Takamine did much to further diplomatic, as well as scientific, relations between these nations. In fact, the illness which resulted in his death may be traced directly to his distinguished service in support of the late Disarmament Conference and to his activities in welcoming the delegates of the Japanese Business Men's Mission and Baron Shibusawa's party.

Dr. Takamine was perhaps best known for his pioneer work in the field of biological and pharmaceutical chemistry. His discovery in 1900 of adrenalin, which he isolated from the glands of sheep, gave us the foundation for bloodless surgery and made possible many difficult operations on the eye, ear, nose and throat. The diastatic enzyme, takadiastase, which bears its discoverer's name, is a remedy known to physicians and chemists all over the world. These two products formed the basis for the important pharmaceutical corporations which were established by Dr. Takamine in the United States and in Japan. Among these are the Takamine Ferment Co., International Takamine Ferment Co., Takamine Laboratory, Inc., and Takamine, Inc., in this country and Sankro & Co., Ltd., in Tokyo. In addition he maintained a chemical and physical research laboratory at Tokyo and a private laboratory at Clifton, N. J.

Dr. Takamine was born on Nov. 3, 1854, the first son of a physician to the Prince of Kaga. He first took up the study of medicine at Osaka, but in 1879 was graduated in chemical engineering from the Imperial University of Japan at Tokyo. The Japanese Government sent the young chemist to study at the University of Glasgow and the Andersonian University at Glasgow. Returning home after 3 years, he was appointed chemist of the Imperial Department of Agriculture and Commerce, which position he held until 1884, when he was sent to New Orleans as a commissioner to the Cotton Centennial Exposition.

In 1885 he married a New Orleans girl, Miss Caroline Hitch, and returned to Japan, where he erected the first superphosphate works at Tokyo. He came again to the United States in 1890 and began the research work that won him his enviable position as a commercial chemist. Following the organization of the different companies to manufacture and distribute his products in the United States, he became interested in introducing a number of useful chemical industries into his native country. Thus he is accredited with having established several Japanese alkali and soda works, fertilizer plants, and dye, chemical and aluminum factories.

Dr. Takamine founded the Nippon Club of New York, the Japan-America Society and the Chemical and Physical Research Society of Japan. He was a member of the Lotos, Chemists', Drug and Chemical and the New York Athletic clubs, the American Chemical Society, the American Institute of Chemical Engineers, the Royal Society of London and the Franklin Institute of Philadelphia.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Business Revival Awaits Strike Settlement

Continued Improvement in Fundamental Business Conditions Is Threatened by Labor Troubles in Mines and Shops—Otherwise the Industrial Situation Is Promising

THE present industrial situation is fraught with difficulties which completely overshadow the importance of recent progress being made toward business improvement. Current developments appear insignificant in comparison with the serious consequences which may follow the present crisis in the coal mines and on the railroads. A crucial stage has been reached in this situation and unless the turn is for the better much of the present tide of business revival will have been stemmed.

The coal miners' and railway shopmen's strikes are beginning to pinch some of our largest and most important industries. Serious effects are being felt by the producers of steel and metal products, many of whom are curtailing their production in order to husband their dwindling supplies of coal. The banking of fifteen blast furnaces and increasing irregularities in steel production are among the early symptoms to be reported. There is scarcely a steel plant, however, that can look forward to more than a 30 days' supply of fuel. The glass and clay products and several other industries are being forced to balance production with their coal piles.

It is an unfortunate commentary on the situation that even without the railway complications, the problem of handling the amount of coal needed for next winter will tax railroad capacity to its limit. It may be safely predicted that if the government's plans do not shortly result in coal production and expeditious transportation, all business will be embarassed and industrial revival will suffer a serious setback.

Unemployment No Longer a Factor

It should be recognized, however, that notwithstanding these labor difficulties there has been a consistent and general improvement in fundamental business conditions. Unemployment, except for the voluntary kind, is no longer a factor in the situation. In fact certain industries, notably iron and steel, automobile, construction and farming, have reported actual labor shortages. The U. S. Employment Service made a survey in July embracing 355 principal industrial centers, and a predominating proportion of these reported improvement. Of 65 leading cities, 52 had more workers employed July 1 than on June 1. There were but 13 decreases and these were all in centers affected by either the textile or the coal strike. In 8 of 12 major manufacturing industries there were increases in the number of persons employed. The largest, 32.1 per cent, was for iron and steel; car building and repairing with an increase of 30.5 per cent was a close second, while the automobile manufacturers reporte an increase of 21.2 per cent.

Were it not for the coal strike th railroads would be handling a volum of freight traffic larger than for an year since 1920. From the low poi of 706,713 cars for the week of Apr 15, revenue freight loadings increase to 877,856 cars for the week of Ju 24—the highest for the year. For t week ended July 15 car loadings we 860,907, which represents an increa of 86,023 cars over the correspondi week of 1921. This also shows th during its second week the shopme strike had no noticeable effect freight movement.

Business failures, which in Januar 1922, had attained a new high reco of liabilities, $115,301,371, have sin fallen, and for June were $38,412,7 This is the smallest for any mon since October, 1920.

Stocks and Exchanges

The financial situation continues be favorable, with an abundance money available at low rates of inte est. Security values after a slight r cession during June have begun mo ing up again. This upward trend representative railroad and industr stocks is shown in the following co pilation of *Wall Street Journal* av ages, which has been made by the I ing National Bank:

	20 Railroads	In ti
Highest for 1919 (May)	$91.13 (Nov.)	$11
Highest for 1920 (Nov.)	85.38 (Jan.)	10
Highest for 1921 (Jan. 15)	77.56 (Dec. 15)	8
Lowest for 1921 (June 20)	65.52 (Aug. 24)	6
Highest for 1922 (July 6)	87.58 (May 29)	9

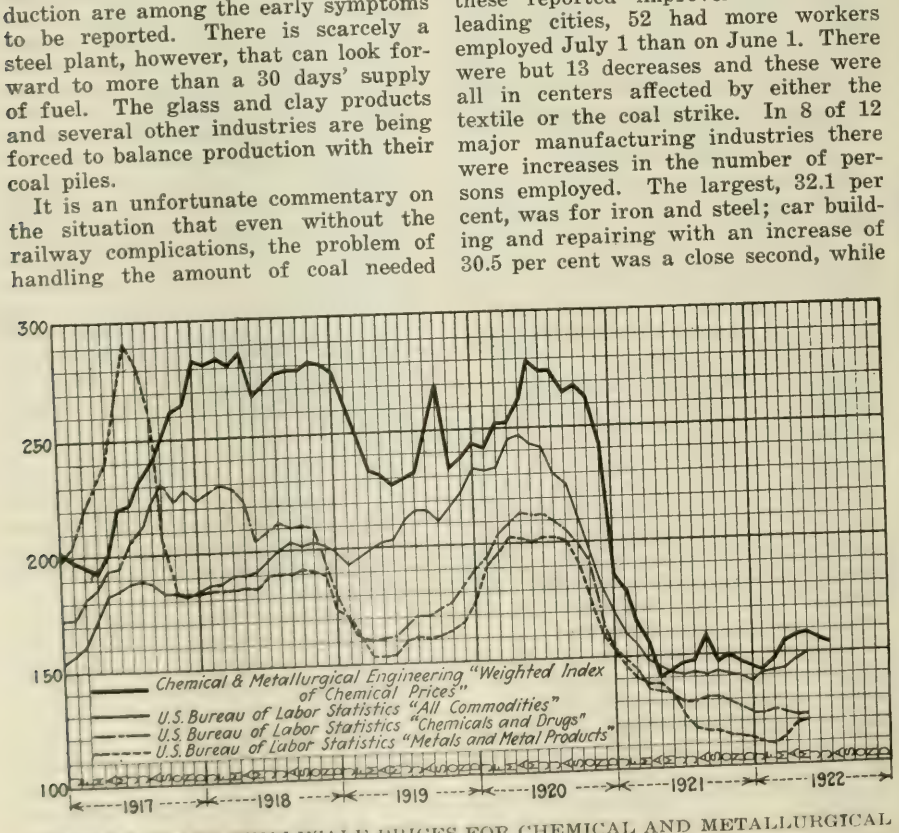
The foreign exchange market b been erratic during the past mon



THE TREND OF WHOLESALE PRICES FOR CHEMICAL AND METALLURGICAL PRODUCTS, 1917-1922

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	153.56
Last week	153.58
August, 1921	158
August, 1920	264
April, 1918 (high)	286
April, 1921 (low)	140

Included in this index are acetic citric, hydrochloric, nitric and sul phuric acids, ethyl and methyl alco hols, ammonia, ammonium sulphate barium chloride, bleaching powder borax, caustic potash, caustic soda copper sulphate, formaldehyde, glyc erine, potassium carbonate, salt cak soda ash, sulphur, benzene, anilin cottonseed and linseed oils.

but except for the German mark, the principal foreign currencies ended the month in a better condition than on June 30. Almost complete demoralization of the Berlin exchange on July 7 forced the value of the mark down to $0.0018¾, a new low level for all time. Following the French negotiations with Great Britain and the possibilities of lowered reparations and a 2-year moratorium, the value of the mark rose to 23c. per 100 on July 12. This level was not long maintained, however, and on July 26 the mark again fell to $0.0019.

Price Trends

Because of seasonal variations and the effects of temporary market conditions, a single month is often too short a time to compare the trend of commodity prices. The Federal Reserve Board's index number based on 100 representative commodities increased from 158 in May to 162 for June. The extent of this improvement is more evident, however, when this index is compared with its value for Jan. 1, which was 142. The Department of Labor "all commodity" index was 150 for June, 1922, as compared with 138 for January. Since the first of the year the index for metals and metal products has increased from 112 to 120, while chemicals and drugs have declined from 124 to 122.

This magazine's weighted index of chemical prices has fallen steadily during July. It averaged 155.61 for the month, as compared with 157.48 for June. The rise from 143.30 on Jan. 1, 1922, to 160.49 on May 24 was apparently too rapid to be of healthy significance and many important commodities have since receded from the temporary peak reached during May. This applies particularly to cottonseed and linseed oils, sulphuric acid, caustic soda, soda ash and barium chloride. Two factors which have contributed to lower prices during the past month are the freight rate reductions which took effect July 1 and the seasonal slackening of demand, which is usually associated with the summer months.

Situation in Individual Industries

Iron and Steel—The situation is reflected somewhat differently in the various chemically controlled industries. Reference has been made to the coal strike's effects on the iron and steel industries, which are already curtailing production. During the month of June, however, some increase was noted. The output of pig iron increased 2½ per cent over May. The unfilled orders of the U. S. Steel Corporation on June 30 showed a considerable gain over the previous month, amounting to 5,635,531 tons on June 30, as against 5,254,228 tons on May 31.

Paper—Total newsprint production during June was 127,230 net tons, but in June, 1921, it amounted to only 86,770. This is equivalent to a gain of 47 per cent. The total for the first 6 months of 1922 is 690,142 tons, as compared with 615,448 tons for the corresponding half of last year. This production is the highest in 5 years, with the exception of 1920.

Automobile—The automobile industry continues to set production records. The June output of passenger cars was 261,963, as compared with 231,724 in May. The steady improvement in the production of trucks, from 23,803 in May to 25,916 in June, may be interpreted as a very favorable index of general business conditions. The month of July is expected to show some seasonal decrease in this industry, but it is estimated that the total yearly output of passenger cars and trucks will be 2,000,000 for 1922, as against 1,668,000 in 1921 and 2,205,197 in the record year 1920.

Petroleum—The petroleum industry has ridden to a fall. May and June productions were but slightly below the record set last March in spite of the fact that consumption of all products except gasoline was unusually low and tremendous oil stocks were piling up. The result has been one price cut after another. Mid-Continent crude had a second cut last week of 25c., bringing it down to $1.50, while crude Pennsylvania oil is selling for $3 a barrel.

Construction—The building boom, which has been gathering momentum in the past 6 months, has resulted in more than doubling the volume of construction completed during the first half of last year. The paint and varnish, structural steel and glass industries have been favorably affected by the increased demand and slightly higher prices for construction materials. The cement industry, stimulated by the demands for both construction and highway programs, has been proceeding at capacity production.

Glycerine Prospects

In the July number of the *Buyers' Bulletin*, issued by Roger Babson's statistical organization, the following interesting comment is made on the glycerine situation:

"For many months the statistical position of glycerine has forced prices to a comparatively low basis. Since 1919 stocks have ruled abnormally large and general business conditions have failed to readjust the situation. Production this year is practically the highest on record and while consumption has also extended upward, an over-supply still exists.

"It will take some time, under present conditions, to reduce current stocks to a level that will justify a broad recovery in price. From an international standpoint the volume of imports is counteracted by exports. This does not mean that a further reaction in price is warranted. A recovery of 7 per cent has already taken place since the low of 1921. Still prices are 27 per cent under the 10-year average prior to 1913. We consider the abnormal situation about discounted by the present range of prices. The next broad movement, although it will not materialize in the immediate future, will be upward and not downward."

The Chemical Market During July

Chemical and allied products showed very few important price changes in the New York market during the past month, due perhaps to the seasonable dullness of the summer months. The railroad situation, the coal strike and tariff uncertainties have greatly retarded possible improvement in business. The export market in alkalis has been somewhat of a disappointment to leading factors, who were of the opinion that prices would be much higher than present levels. Financial difficulties in Germany and the fluctuating exchanges are said to be the direct causes for the declining market.

Sharp Cut in Formaldehyde a Feature

A feature of special interest was the sharp cut in the price of formaldehyde. During the month manufacturers, eager for passing business, quoted prices as low as 7¼c. per lb., the lowest level recorded since the war. During the latter part of July, however, producers were pressed for deliveries and prices were brought back to 8@8¼c. per lb. Prussiate of soda, barium chloride, caustic potash and potash alum have recorded slight decreases during the interval, due to increasing stocks and lack of interest from consumers. In contrast with these declines there was a significant advance in white powdered arsenic. Insecticide manufacturers have reported a phenomenal demand and spot material has become very scarce. Prices were advanced from 7c. to 7⅞c. per lb. Oxalic acid was another item that showed considerable strength during the month. Producers announced an advance at the works from 14c. to 14½c. per lb. early in the month and quotations have held very steady throughout the interval, with consumers buying in moderate quantities.

Calcium Acetate Prices Increased

Calcium acetate prices were increased on two occasions during July owing to the decreased spot supplies and the increasing demand. The first advance was from $1.75 to $2 per 100 lb. The following week another advance of 35c. per 100 lb. was announced, bringing the spot market to $2.35 per 100 lb. Acetone and all grades of acetic acid were advanced to correspond with the lime acetate market. Sulphate of ammonia, copper sulphate, acetate of soda and prussiate of potash have shown considerable strength, with fractional advances recorded among first hands.

It may be stated in general that the markets during July revealed few surprises to the professional trader. Nor is there any reason to believe that the coming months will bring about any disastrous results, but, on the contrary, producers are very optimistic about the fall season and are looking forward to a resumption of real business with the industries that consume chemicals and related materials.

The New York Market

NEW YORK, July 31, 1922.

The chemical market during the past week continued along the same quiet lines in evidence during the preceding week. Trading in most instances was for immediate consumption, with the general tone extremely conservative. There were a few important price changes, foremost among which was the decrease noted in caustic soda for export. Trading has shown a decided improvement since the last decline and leading producers are looking forward to a much firmer market in the near future. Oxalic acid was reported fractionally higher at the works. White powdered arsenic continued firm, with only odd lots available. Acetate of soda was decidedly strong and buyers found some difficulty in getting any round quantities. All grades of acetic acid recorded advances to correspond with the recent rise in calcium acetate. Copper sulphate continued very firm. Insecticide dealers have been in this market for large tonnages and no let-up is in sight for the next few weeks. Cyanide of potash has been very scarce of late and prices showed an advance from 50@55c. per lb. The spot market is very firm.

GENERAL AND SPECIAL CHEMICALS

Ammonium Sulphate—Restricted production has kept this item rather short on spot, with the demand much greater than the supply. It is doubtful if better than $3.55 per 100 lb. could be done for double bags, f.a.s. N. Y.

Arsenic — Leading factors quote the market very firm at 7½c. per lb., prompt shipment. There have been a few odd lot sales among second hands at 7¾@8c. per lb. The demand is brisk.

Acetic Acid—Higher prices for calcium acetate have caused an advance in all grades of this acid. The 28 per cent is quoted at $2.60 per 100 lb., with the 56 per cent at $5.25 per 100 lb. Glacial acetic is held around 11c. per lb. in barrel lots. Demand is moderate.

Acetone—Prices for acetone were advanced by makers in order to correspond to the increase on acetate of lime. Chemically pure acetone is selling at 13@13½c. per lb. for carlots, with smaller quantities at 14@15c. The general market is firm.

Bichromate of Soda — Some small transactions were recorded at 7c. per lb., with quantity lots down to 6¾c. Trading was only moderate with the call mostly for contract shipments.

Bicarbonate of Soda — Producers quote the market around $1.75 per 100 lb., in barrels. The general tone of the market is steady, considering the time of the season.

Caustic Soda — There was another decline in this product to $3.50 per 100 lb. f.a.s. The demand was much better from the Orient and various European centers. Contract prices are nominally unchanged.

Copper Sulphate — There was a healthy tone to this market, especially from the insecticide industry. Dealers quote 6½@6¾c. per lb. for limited quantities on spot.

Formaldehyde—Producers have withdrawn from the market and goods previously quoted down to 7½c. per lb. could not be located in any quarters. Second hands quote the spot market at 8@8½c. per lb. Demand is moderate.

Muriate of Potash — Following increased importations there has been a slight decrease in this item from $33.50 per ton to $33. There were some larger sales reported fractionally lower than this but the general range is from $33@$33.50 per ton.

Prussiate of Soda—Trading has been rather dull during the interval and prices ranged around 20½c. per lb. for spot goods. Shipments from abroad were quoted from 19½@20c. per lb. c.i.f., duty paid.

Oxalic Acid — Spot quotations were held at 15¼@15½c. per lb. The best price heard at the works was 14½c. per lb. Demand is much better, with consumers showing more interest in spot goods.

WAXES

Beeswax—The market for African crude was rather steady both here and abroad. Offerings in several directions were limited, with spot quotations around 24@25c. per lb. Brazilian crude held at 28@29c. per lb.

Candelilla Wax—There were only a few offerings on spot at 40c. per lb. The demand far exceeds the limited supply.

Carnauba Wax—Prices in all grades have undergone little change. Shipments have increased notably of late, but prices were somewhat steady during the week. No. 3 North Country held at 16½@17c. per lb. No. 2 was quoted at 22@24c. per lb.

Japan Wax — The market did not show any signs of live trading and prices remained unsteady at 16½@17c. per lb. Forward business was transacted at 15c. per lb., in large lots.

Montan Wax—Prices were not very strong in this item. Spot material is in liberal supply with competition very keen. The market closed at 3¾@4c. per lb.

Paraffine Wax—There was little demand during the past week, but prices remained steady. Crude scale of 122-124 deg. melting point was held at 2½@2¾c. per lb., for carload quantities.

The Chicago Market

CHICAGO, July 25, 1922.

There was a little more life to the chemical market during the past week and buyers appeared to be interested in larger quantities. The rail strike probably had considerable to do with this, as supplies from the East were coming in slower than usual. The tone of the market is firm, with only a very few declines to be noted. Higher prices in the spot market were predicted unless there is an early settlement of the coal and rail strikes. Imported material is as firm as domestic in this market and no heavy stocks of either could be located.

GENERAL CHEMICALS

Caustic soda was a trifle easier on spot and supplies were available at $3.80 per 100 lb. for the 76 per cent solid and $4.35 for the ground. *Caustic potash* was firmer, with most holders asking 6¾@6¾c. per lb. for the imported 88-92 per cent material. *Soda ash* was unchanged at $2.20@$2.30 per 100 lb. for the 58 per cent material in cooperage.

Alums were unchanged both as to price and demand. *Ammonia alum* was available in second hands at 3¾@4¼c. per lb. for the lump and 4¼@4¾c. for the ground. *Potash alum* moved in a fair volume at 4½@5c. per lb. for the iron-free lump and 5½@6c. for the U.S.P. powdered. *Sal ammoniac* was quiet, with open quotations unchanged at 7¾@8c. per lb. for the white granular. It is possible that the lower figure could have been shaded fractionally with a fair-sized inquiry. *Copper sulphate* displayed no signs of weakness, and quotations were firm at 6½@7c. per lb. *Carbon bisulphide* was in good demand and supplies were more plentiful at 7@7½c. per lb. *Carbon tetrachloride* was reported as moving in a fair way at 10@10½c. per lb. for the large drums. *Formaldehyde* was somewhat more active, although the price was unchanged at 9c. per lb. for single-barrel lots. *Glycerine* was firmer and refiners were asking 16c. per lb. for the c.p. material in large drums. *Red phosphorus* was available at slightly lower prices from second hands, who apparently had all the business at 25@26c. per lb. for single-case lots.

No improvement was to be noted in *bichromates*. *Potasium bichromate* was quoted at 11c. per lb. in single-cask lots and *sodium bichromate* at 8½@9c. in similar quantities. *Red prussiate of potash* continued exceedingly scarce with only small lots available at 90c.@$1 per lb. The yellow salt was in about the same position as before and was offered at 32@35c. per lb. *Potash permanganate* lacked quotable change and the U.S.P. small crystals were available at 15½@16c. per lb. *Hypo* was reported to be moving in the usual consuming channels at $3.85 per 100 lb. for the pea crystals in barrels.

LINSEED OIL

The movement of *linseed oil* was rather slow during the past few days and the market was reported as weaker. The boiled oil was quoted late today at 95c. per gal. in 5-drum lots, with similar lots of the raw at 93c.

NAVAL STORES

Turpentine, like linseed oil, has been moving only in a small volume during the past few days, with the tendency of the market downward. Five-drum lots were quoted today at $1.22½ per gal. *Rosin* was in better demand and the WG grade was offered in less than carlots at $8.75 per 280 lb.

The Iron and Steel Market

PITTSBURGH, July 28, 1922.

The combination of the railroad rike begun 4 weeks ago and the coal rike begun 4 months ago is the dom- ant factor not only in the iron and eel trade but in industry generally. al supplies, which increased during e first 3 months of the coal strike, ve decreased sharply since transpor- tion difficulties arose.

It is now much more than a matter whether pig iron and steel can be oduced. It is a question also of ether the pig iron and steel can be nsumed. Thus far there is little if y indication that industrial opera- ns have been slowed down at any int through lack of steel, but it seems ogether probable that there will be slowing down in steel consumption, rough insufficiency of transportation d of coal supply.

STEEL INGOT PRODUCTION

Steel ingot production reached its aximum rate toward the close of ne, having increased rapidly in the st 3 months of the year and slowly ereafter. There has since been a de- ease, and by this time the decrease ay amount to between 5 and 10 per nt. The influence of diminished coal pply is felt first at byproduct coke ens, rather than in coal for heating d rolling steel. Some byproduct ovens were running on a hand-to-mouth basis, others had small stocks, none probably sufficient for 30 days' opera- tion. The banking and blowing out of blast furnaces comes more promptly at some points than at others, being es- pecially noticed in eastern Pennsylvania and in the Mahoning and Shenango Valleys. Unless conditions change promptly and radically for the better many more furnaces will have to stop.

The effect of the new situation upon the steel market has been for buyers and sellers to cease considering late de- liveries at all, and to increase the pres- sure to buy small lots for early ship- ment, as a result of which delivery premiums have increased in some cases. Basis prices, for extended de- livery, are not greatly affected, except that mills are somewhat stiffer in their views, finding that with restricted pro- duction the tonnage they had on books will keep them occupied a longer time than they estimated a month ago. The minimum price on bars, shapes and plates is now 1.70c. instead of 1.60c., this being for indefinite delivery, on orders that prove attractive to mills. Former prices of 2.40c. on blue an- nealed sheets, 3.15c. on black, and 4.15c. on galvanized sheets are not entirely lost, but it is very difficult to make pur- chases except at $2@$3 a ton higher.

Offerings of Connellsville coke are lighter and prices are higher, being quotable at $13.50@$14 for furnace coke and at $14.50@$15 for foundry coke. Blast furnaces disappeared from the market long ago, and most other consumers, except foundries, have since disappeared, while foundries are buy- ing but little in proportion to their normal requirements. As a matter of fact, the quotations on the respective grades may be taken to mean that coke offered as "foundry" grade is more or less of that grade, while coke sold as "furnace" coke is for foundry use, but is not at all guaranteed as to grade.

Connellsville steam coal has sold up to $8.50 and Westmoreland County gas coal up to $9.50, but how much of the coal recently bought and sold will get through, now that the priority system is established on the railroads, is a question.

PIG IRON PRICES

Production of merchant pig iron has dwindled to almost insignificant pro- portions, as has inquiry. Any forced purchases would no doubt cause sharp advances in market prices, but con- sumers seem indisposed to bid for the limited quantities of pig iron in exis- tence or likely to be made in the next few weeks. On the basis of last sales the market is quotable at $25 for besse- mer, $24 for basic, $27 for malleable and $25 for foundry, f.o.b. valley fur- naces, but these prices are largely nom- inal, it being uncertain whether any business could be done at such prices.

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.14 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.65 — .67
Benzoate of soda, U.S.P.	lb.	.53 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.23 — .26
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.21 — .22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Dipnenylamine	lb.	.55 — .58
H-acid	lb.	.85 — .95
Meta-phenylenediamine	lb.	.85 — 1.00
Monochlorbenzene	lb.	.10 — .11
Monoethylaniline	lb.	1.00 — 1.20
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06¼ — .07
Naphthalene, balls	lb.	.07¼ — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	$0.15 — $0.17
N-W acid	lb.	1.15 — 1.30
Ortho-amidophenol	lb.	2.15 — 2.25
Ortho-dichlor-benzene	lb.	2.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75
Ortho-nitro-toluene	lb.	.10 — .13
Ortho-toluidine	lb.	.14 — .18
Para-amidophenol, base	lb.	1.30 — 1.35
Para-amidophenol, HCl	lb.	1.35 — 1.40
Para-dichlorbenzene	lb.	.17 — .20
Paranitroaniline	lb.	.72 — .80
Para-nitrotoluene	lb.	.55 — .65
Para-phenylenediamine	lb.	1.55 — 1.60
Para-toluidine	lb.	.90 — 1.00
Phthalic anhydride	lb.	.35 — .38

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

LEATHER—The Charles S. Walton Co., Philadelphia, Pa., tanner of sole and belting leathers, has placed its tannery at Curtis Bay, Baltimore, Md., on a full capacity basis, with regular working force.

The General Leather Co., Frelinghuysen Ave., Newark, N. J., specializing in automobile leathers, is developing maximum capacity at its plant. The company has recently placed its new addition in service, giving the plant a capacity of 1,200 salted hides per day.

The Greiss-Pfleger Tanning Co., Cincinnati, O., has increased production at its tanneries at Chicago and Waukegan, Ill. The June shipments from the plants were the largest in the history of the company.

A number of leather tanneries at Newark, N. J., are advancing operations to a close to normal basis, including Straus & Sons, and the Fr[illegible]d Brothers Leather Co. Imitation leather (cau[illegible]mpanies in this section also are wor[illegible]ntracts. [illegible]an advanced production schedule. [illegible]ide (caus[illegible]

CERAMIC—The C[illegible]kling-Armstrong Terra Cotta Co., Philadelphia, Pa., has adopted a capacity operating basis at its plant, and a number of departments are now running on an overtime schedule.

The National Fireproofing Co. is maintaining active production at its plant at Port Murray, N. J., giving employment to a large working force.

IRON AND STEEL — The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., has resumed operations at another blast furnace, making a nine-furnace base for the company, six producing basic iron, two running on foundry pig, and one on ferromanganese.

The Eastern Steel Co., Pottsville, Pa., has blown in two blast furnaces at its local plant, following an idle period of many months. Every department of the works is now in service, and operations will be increased in different branches at an early date.

The United States Steel Corp., New York, has advanced production at its different mills to a 76 per cent of normal operating basis.

The Carnegie Steel Co. is operating its six blast furnaces at Youngstown, Ohio, at full capacity on large merchant bar.

The coal strike and railroad strike have caused the suspension of a number of blast furnaces, heretofore running at capacity up to about a week ago. These include two bessemer furnaces of the Republic Steel Co. and one furnace of the Trumbull-Cliffs Iron Co., both in the Youngstown, O., district. The Briar Hill Steel Co., in the same section, has banked one of its furnaces. The Bethlehem Steel Co. has placed three of its furnaces out of blast, two being at the Bethlehem, Pa., works, and the other at Steelton, Pa. At Cleveland, O., the McKinney Steel Co. has banked one of its furnaces.

The Youngstown Sheet & Tube Co., Youngstown, O., is now running at close to 80 per cent of normal.

METALS — The Cerro de Pasco Copper Corp., New York, will soon place its new smelting plant at Oraya, Peru, in operation. The plant will run on a basis of 2,500 tons of ore per day, the ore being estimated to average from 5 to 6 per cent of copper.

The Bartlesville Zinc Co., Bartlesville, Okla., is increasing production at its plant at Blackwell, Okla. The wages of employees have been advanced 50 cents a day, making an increase of over one dollar a day since the company reopened its plant a few months ago.

The Calumet & Hecla Copper Co., Calumet, Mich., is operating on a production basis of about 4,000,000 lb., refined, per month; of this amount, about 1,500,000 lb. is being secured from the reclamation plant.

PAPER — The United Paper Board Co., Lockport, N. Y., is running on a capacity basis at its local mill. A general increase of 10 per cent has been made in wage schedules.

The International Paper Co. has increased operations to four machines at its plant at Three Rivers, Que., with output totaling 240 tons per day.

MISCELLANEOUS — The United States Guano Co., Standard Wholesale Phosphate Co., Union Acid Works, Standard Guano Co. and the Standard Acid Works, all of Baltimore, Md., and operated under one management, manufacturing fertilizer products, are increasing production at their plants. Extensions are under way to utilize the escaping gases for chemical reclamation.

The Chattanooga Coke & Gas Co., Chattanooga, Tenn., is arranging for the early resumption of operations at a portion of its plant.

Tire production at Akron, O., is now running close to 105,000 tires a day at all plants combined, which are giving employment to about 50,000 men and women.

The Midwest Castings Co., Middletown, O., is arranging for the immediate resumption of operations, following a shut-down for close to a year past.

Owing to fuel shortage, the American Sheet & Tin Plate Co., Youngstown, O., has closed 26 mills at its Farrell, Pa., works. The suspension is temporary.

The Three Rivers Glass Co., Three Rivers, Tex., will soon commence production at its new local plant. The building has been completed and machinery installation is under way. H. S. Warwick is manager.

The Whitall-Tatem Co., Millville, N. J., has placed two of its glass factories out of blast, and will commence immediate repairs to the furnaces and other plant departments. Resumption is planned early in the fall.

Construction and Operation

Arkansas

VAN BUREN—J. H. Hansel, Ozark, Ark., is organizing a company to establish a local plant for the manufacture of brick and other burned clay products. A site is being selected.

California

MARTINEZ—The Shell Oil Co., 343 Sansom St., San Francisco, has plans under way for the installation of a new still and other equipment at its local refinery, estimated to cost about $150,000.

OAKLAND—The Fornercrete Aggregate Co., manufacturer of cement specialties, colors, etc., for exterior construction, has leased property on Clement St., near High St., totaling about 30,000 sq.ft., as a site for the erection of a new plant. Plans will be prepared at once. E. K. Forner is president. The Industrial Department of the local Chamber of Commerce is interested in the project.

LOS ANGELES—The Pacific Coast Borax Co., Kohl Bldg., San Francisco, has acquired a tract of property in the harbor section, formerly occupied by the Chandler Shipbuilding Co., totaling about 10 acres of land, as a site for the erection of a new refining plant. It is estimated to cost close to $1,000,000, including machinery, and will handle the deposits from the company's property in Death Valley, Cal.

SACRAMENTO—The Pacific Gas & Electric Co., 445 Sutter St., San Francisco, will make extensions and improvements in its local artifical gas plant to cost about $150,000, including equipment.

IRVINGTON—The Panama Soap Co., San Diego, is negotiating with the city trustees for a suitable site for the erection of a new local plant for the manufacture of soaps and kindred products. It is proposed to remove the present works from San Diego, and discontinue operations entirely at this latter location.

SAN DIEGO—The Vitrified Products Corp. has purchased property in the Oldtown district, and plans for the erection of a new plant for the manufacture of shale brick. The equipment installation will provide for automatic operation, without handling after production has been commenced.

SANTA CLARA—The Concrete Lumber Co. is negotiating with the local Chamber of Commerce for a suitable site for the erection of a new plant. The company is now located at Los Angeles.

Colorado

TELLURIDE—The Tomboy Mine & Milling Co. has tentative plans under consideration for the rebuilding of the portion of its plant destroyed by fire, July 8, with loss estimated at about $50,000, including equipment.

Connecticut

MERIDEN — The Tredennick Paint Co., South Colony St., has commenced the erection of a new 1-story plant addition.

Illinois

JOLIET—The Illinois Wall Paper Co., a subsidiary of the York Card & Paper Co., York, Pa., is completing plans and will soon take bids for the erection of a new 1-story plant on Logan St., 100x300 ft., estimated to cost about $85,000. R. G. Hoen, 417 National Bank Bldg., Joliet, is architect. Robert D. McCoy is president.

Indiana

INDIANAPOLIS—The Beveridge Paper Co., Pearl St., has plans under way for the erection of a new building at its local plant. H. L. Beveridge is president.

JEFFERSONVILLE—The Louisville Cement Co., Louisville, Ky., has tentative plans under consideration for the rebuilding of the portion of its manufacturing plant at Speeds, near Jeffersonville, destroyed by fire, July 13, with loss estimated in excess of $300,000, including equipment.

Louisiana

NEW ORLEANS—The Chalmette Petroleum Corp., recently organized, has acquiired the plant and property of the Chalmette Oil Refining Co. and the Louisiana Oil Exporting Co., and will consolidate the interests. Plans are under way for extensions in the oil refining plant for considerable increase in capacity. The new company will operate with a capital of $1,000,000.

LAFAYETTE—The Guidry Brick Co. is planning for extensions to double, approximately, the present plant capacity. A. Guidry heads the company.

Maryland

BALTIMORE—The United States Asphalt Refining Co., has filed plans for the erection of a 1-story building, 33x70 ft., at North and 4th Aves.

Massachusetts

AMHERST—The Amherst Agricultural College has awarded a contract to George S. Allen, Amherst, for the erection of its proposed new 3-story and basement chemical laboratory, 94x195 ft., estimated to cost about $300,000, including equipment. Ritchie, Parsons & Taylor, 15 Ashburton Place, Boston, are architects.

Michigan

DETROIT—Porath Brothers are considering preliminary plans for the rebuilding of the portion of their brick and clay products manufacturing plant, destroyed by fire July 9, with loss approximately $50,000, including equipment.

MOUNT PLEASANT—The National Portland Cement Co. has excavation work under way for the initial buildings at its new plant at Coldwater Lake, and will commence foundations and superstructure at an early date. The main mill will be 2-story, and will be supplemented with number of other buildings, including power plant, etc. The entire plant will cost about $500,000, including machinery. A. E. Gorham, 119 South Normal St., Mount Pleasant, is president.

Mississippi

HATTIESBURG—The Hattiesburg Pine Oil Co., recently organized with a capital of $425,000, has plans under way for the erection of a new plant on local site for the manufacture of pine oil, turpentine and kindred products. The mill is estimated to cost in excess of $75,000, with machinery. The company is headed by M. D. King and Paul S. West, both of Hattiesburg.

Missouri

ELVINS—The St. Louis Smelting & Refining Co., 722 Chestnut St., St. Louis, h

plans completed for the establishment of a local plant, in connection with extensive property developments on a tract of 650 acres. The project is estimated to cost close to $500,000, including machinery.

ST. LOUIS—Benjamin Moore & Co., Inc., manufacturer of paints, varnishes, etc., is reported to be planning for the immediate rebuilding of the portion of its plant on South Second Street, destroyed by fire, July 8. A number of plant buildings and equipment were damaged. An official estimate of loss has not been announced.

KANSAS CITY—The Acme White Lead Co., Detroit, Mich., will commence work at once on remodeling and improving its local plant building at 15th and Grand Sts. The Bliss Building Co., 402 Mutual Bldg., Kansas City, has the construction contract.

New Jersey

ELIZABETH—The Atlantic Tar & Chemical Works, Ltd., Rayway, Elizabeth, manufacturer of coal tar products and other chemical specialties, has plans in progress for enlargements in its plant for considerable increase in capacity. Additional equipment will be installed. To carry out the expansion, the company has arranged for a bond issue of $500,000, the larger part of the proceeds to be used for such purpose. George C Lewis is president, and David Viener, vice-president and general manager.

NEWARK—Walter G. Jacobs, 9 Campbell St., operating a foundry for the manufacture of iron and other metal castings, has commenced the erection of a new 3-story plant at 63-73 Warren St., estimated to cost in excess of $75,000. Contract for the building has been let to the American Concrete Steel Co., Essex Bldg.

BLOOMFIELD—The Standard Oil Co. of New Jersey, 31 Clinton St., Newark, has filed plans for the construction of a new distributing plant and substation in the Silver Lake district, estimated to cost about $42,000.

PERTH AMBOY—The American Smelting & Refining Co., 120 Broadway, New York, has work under way on improvements at its local copper-refining plant, and expects to have the unit ready for service early in October.

New Mexico

TUCUMCARI—The Pecos Co. is perfecting plans for the completion of its local oil refinery, and will proceed with the work at an early date. The construction has been held in abeyance for a number of months past. The plant will be placed in service immediately upon completion.

CARRIZOZO—The Helen Rae Mining Co., will make a number of improvements in the mill at its local gold mining properties. The plant has been closed temporarily for this purpose; the machinery will be repaired.

New York

GOWANDA—The Eastern Tanners' Glue Co., has plans under way for the erection of a new plant on Palmer St. Richard Wilhelm is president.

NEW YORK—The Nevada Consolidated Copper Co., 25 Broad St., will soon commence the rebuilding of the concentrating plant at its properties, recently destroyed by fire with loss approximating $1,500,000, including machinery. The plant had a capacity of about 12,000 tons, and the new unit is expected to be of like size. The smelting plant at the property was not damaged by the fire and will be continued in operation.

Oklahoma

TULSA—The Phillips Petroleum Co., Bartlesville, Okla., has plans under way for the erection of a new gasoline absorption plant on site selected at DeNoya, near Tulsa. The plant is estimated to cost about $500,000, including compressors, pumps and other operating machinery, and will be one of the largest plants of this character ever built.

OKLAHOMA CITY—The City Commission has approved plans as prepared for a new water-purification plant at the municipal waterworks, and expects to call for bids at an early date. The city engineer is in charge.

Oregon

WILLIAMINA—The Oregon Face Brick Co., 204 Henry Bldg., Portland, has acquired a brick manufacturing plant at Wilamina, and will place the works in operation at once. A number of improvements will be made. Local clay deposits have also been purchased for raw material supply. Robert Shelley is president.

Pennsylvania

PHILADELPHIA—The Gilbert Spruance Co., 312 North 3rd St. manufacturer of paints, varnishes, etc., has awarded a contract to Harry Gill, Jr., 2515 Germantown Ave., for the erection of a 2-story factory addition, 70x138 ft., at Richmond and Tioga Sts., estimated to cost about $47,000.

MCKEES ROCKS—The Chesebrough Mfg. Co., 17 State St., New York, a subsidiary of the Standard Oil Co., manufacturer of vaseline and byproducts, is completing plans for the first unit of its proposed new local plant, and will call for bids at an early date. It will be 2 and 3 story, and is estimated to cost close to $500,000, including machinery. Other plant units will be built at a later date. The company recently acquired a tract of about 14 acres of land near McKees Rocks for the works. The Hunting-Davis Co., Century Bldg., Pittsburgh, is architect and engineer.

PITTSBURGH—The Watson Paint & Glass Co., 101 Wood St., has purchased from E. A. Campbell the factory of the Eagle Paint & Varnish Co., Galveston Ave., recently acquired by the latter. It is planning to occupy the property for extensions in its present works.

PITTSBURGH—The Atlantic Refining Co., Butler and 56th Sts., is considering preliminary plans for extensions in its local refining plant. Headquarters of the company are at 3144 Passyunk Ave., Philadelphia.

LOCK HAVEN—The General Refractories Co., Oliver Bldg., Pittsburgh, has purchased the local plant and property of the Hayes Run Fire Brick Co., Orviston, near Lock Haven, and will continue operations at the plant as heretofore. The company will be merged with the parent organization, which also recently acquired the plant and property of the Pennsylvania Fire Brick Co., Beech Creek, Pa.

South Carolina

PAMPLICO—The Consumers' Oil Co., is reported to be planning for the rebuilding of the portion of its plant, recently destroyed by fire.

Texas

STAMFORD—The Rule-Jayton Cotton Oil Co., has acquired local property, totaling about 20 acres, for the erection of a new cotton oil mill. Plans for the structure are under way. It is estimated to cost close to $150,000, including equipment. The mill will have an initial capacity of about 125 tons per day.

CHILDRESS—The City Council will commence the immediate construction of the proposed new filtration plant at the municipal waterworks, estimated to cost about $30,000.

EL CAMPO—The plant and property of the El Campo Oil Mill Co., has been acquired by H. E. Wilson, Wharton, Tex., and associates. The new owners will organize a company to operate the plant, and will make a number of improvements in building and equipment. It is expected to have the mill in regular service at an early date.

BEAUMONT—A portion of the local distillate plant of the Magnolia Petroleum Co., including storage tanks, etc., was destroyed by fire, July 15, with loss estimated at about $1,500,000, including equipment and sock.

Washington

CAMAS—The Crown Wilmette Paper Co., is reported to be planning for the erection of an addition to its plant on adjoining property, recently acquired.

West Virginia

GRAFTON—George W. Bowers, Mannington, W. Va., is perfecting plans for the organization of a new company and the establishment of a local plant for the manufacture of pottery products. A site will be secured at an early date.

Canada

ASBESTOS, QUE.—The Johns-Manville Co., Madison Avenue and 41st St., New York, manufacturer of asbestos products, has acquired property here and plans for the erection of a large Canadian branch plant. The proposed works will consist of a number of buildings, including power plant, etc., and will be equipped to give employment to about 300 persons. The plant is estimated to cost close to $1,000,000. The company has also purchased the mining properties of the Bennett-Martin Co., at Thetford Mines, Que., in the same vicinity, and will use as a source of raw material. It is expected to have the initial plant unit ready for operation early in 1922. T. F. Manville is president.

Capital Increases, Etc.

THE BUFFALO COLD DRAWN STEEL CO., INC., Buffalo, N. Y., has filed notice of increase in capital from $2,000,000 to $3,500,000.

THE KOENITZER TANNING CO., Saginaw, Mich., has filed notice of decrease in capital from $325,000 to $100,000.

THE BULLET PROOF & NON-SHATTERABLE GLASS CORP., recently organized under New York laws, has filed notice to operate in New Jersey for the manufacture of special glass products. The company is represented by Edward S. Bock, 45 South Spring St., Elizabeth, N. J.

THE BOSTON LEATHER & FINDING CO., Bridgeport, Conn., has filed notice of increase in capital from $20,000 to $50,000.

THE YORKTOWN OIL & MFG. CO., Yorktown, Tex., has filed notice of increase in capital from $50,000 to $100,000.

THE BARAGUA SUGAR CO., 25 Broad St., New York, N. Y., operating a sugar refinery in Camaguey Province, Cuba, is disposing of a bond issue of $4,500,000, a portion of the proceeds to be used for general expansion. Edwin F. Atkins is president of the Punta Alegre Sugar Co., the parent organization.

THE NITRO PRODUCTS CO., Saginaw, Mich., has filed notice of reduction in capital stock from $200,000 to $20,000.

THE CONSTANTIN REFINING CO., Tulsa, Okla., has arranged for a bond issue of $720,000, a portion of the proceeds to be used for general expansion.

THE MUTUAL OIL CO., Denver, Col., will increase its capital stock from $15,000,000 to $30,000,000, a portion of the proceeds to be used for expansion, including the purchase of additional oil properties and refineries.

THE NIAGARA FELT & PAPER CO., Little Falls, N. Y., has filed notice of increase in capital from $60,000 to $200,000.

THE ILLINOIS-KANSAS OIL & GAS CO., Tulsa, Okla., has filed notice of increase in capital from $500,000 to $1,000,000.

THE FIBERBILT SPECIALTIES, INC., 427 Broadway, New York, N. Y., has filed a petition in bankruptcy. Edward McDonald has been appointed receiver.

THE DETROIT EMERY WHEEL CO., Detroit, Mich., has filed notice of dissolution under state laws.

New Companies

THE SUNSET RUBBER CO., Everett, Wash., has been incorporated with a capital of $150,000, to manufacture rubber specialties. The incorporators are C. E. Powley and W. A. McCloud, both of Everett.

THE WOODBRIDGE PRODUCTS CO., 123 Main St., Woodbridge, N. J., has filed notice of organization to manufacture lubricants, soaps, etc. The company is headed by George M. Anderson and LeRoy F. Kendall.

THE R. T. CLARK OIL CORP., Natchez, Miss., has been incorporated with a capital of $2,000,000, to manufacture petroleum products. The incorporators are R. T. Clark, Natchez; L. S. McFadden and R. L. Cheshire, both of Monticello, Ark.

THE SHINGLE-GIBB LEATHER CO., Philadelphia, is being organized by Lester H. Shingle, Walton and Thomas B. Gibb, 503 Chestnut St., to manufacture leather products. Application for a state charter will be made at once. The last noted incorporator represents the company.

THE EASLEY OIL CO., Pittsburgh, Pa., is being organized by Edwin A. Easley, S. A. Doherty and F. B. Carraher to manufacture oil products. Application for a state charter will be made on July 24. The company is represented by James F. Coyle, 1513 Berger Bldg., Pittsburgh.

THE ASPHALT ROOFING PRODUCTS CO., care of the Colonial Charter Co., Ford Bldg., representative, has been incorporated under state laws with a capital of $25,000, to manufacture prepared roofing specialties.

THE MOUND CITY LINSEED OIL CO., St. Louis, Mo., has been incorporated with a capital of $5,000, to manufacture linseed oil products. The incorporators are W. H. Wilkins, G. S. Sturges and J. J. Rufile, all of St. Louis.

THE PETROLEUM CORP., Wichita Falls, Tex., has been incorporated with a capital of $75,000, to manufacture petroleum products. The incorporators are F. W. Fischer, S. I. Carter and D. E. Ducas, all of Wichita Falls.

THE ENAMELART FINISHING CO., New York, N. Y., has been incorporated with

a capital of $10,000, to operate an enameling works. The incorporators are F. E. Pearson, G. S. Nobles and L. J. Schneider, 116 West 90th St., New York.

THE BROWN CLAY PRODUCTS Co., Canton, Ohio, has been chartered under state laws to manufacture brick and other burned clay products. The incorporators are Ira E. Brown and O. E. Smith, both of Canton.

THE AETNA EXTERMINATORS, INC., 3407 North Halsted St., Chicago, Ill., has been chartered under state laws to manufacture chemical products, insect powders, etc. The incorporators are A. U. Forman, Hulda Almert and Andrew H. Almert.

THE GUY STEEL CASTINGS Co., West Hartford, Conn., has been incorporated with a capital of $50,000, to manufacture steel and other metal castings. The incorporators are George B. Kinghorn, Southington, Conn.; J. E. Sinnott, Hartford, Conn., and W. R. Bennett, 249 Fairfield Ave., Hartford. The last noted represents the company.

THE PEERLESS OIL Co., Mannington, W. Va., has been incorporated with a capital of $700,000, to manufacture petroleum products. The incorporators are Jesse Shimp, E. B. Koen, both of Mannington and James A. Meredith, Fairmont, W. Va.

THE DE COTIIS CHEMICAL & COLOR Co., Pittsburgh, Pa., is being organized by A. De Cotiis, Roy Rhea and C. Schoemer, to manufacture paints, colors, chemicals, etc. Application for a state charter will be made on August 8. The company is represented by Duff, Marshall & Davis, 408 Union Arcade Bldg., Pittsburgh.

THE HARVARD CHEMICAL Co., Boston, Mass., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by John J. Palladino, 22 Dartmouth St., Boston.

INTERNATIONAL INKS, INC., Trenton, N. J., care of the Corporation Bureau of New Jersey, 33 West State St., Trenton, representative, has been incorporated with a capital of $1,000,000, to manufacture inks of various kinds, colors, etc.

D. D. JOHNSON & Co., LTD., 138 South Schuyler Ave., Kankakee, Ill., has been incorporated with a capital of $50,000, to manufacture chemical fungicides and other chemical specialties. The incorporators are David D. Johnson, C. H. Rumley and Lee E. Horton.

THE SHOPE BRICK Co., South Bend, Ind., has been incorporated with a capital of $25,000, to manufacture brick and kindred products. The incorporators are George J. Hoffman, Clem C. Whiteman and Richard Johnson, all of South Bend.

THE INTERNATIONAL PETROLEUM PRODUCERS, INC., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws with capital of $1,000,000, to manufacture petroleum products.

THE BUMET RUBBER Co., East Orange, N. J., care of the New Jersey Registration & Trust Co., 525 Main St., East Orange, has been incorporated under state laws with a capital of $50,000, to manufacture rubber products.

THE CRAGEN OIL & REFINING Co., 24 North Main St., East St. Louis, Ill., has been chartered under state laws to manufacture refined oil products. The incorporators are Edward L. Cragen, Daniel T. Garber and Joseph A. Troy, Jr., all of East St. Louis.

THE GARDAPLANT CHEMICAL Co., St. Joseph, Mo., has been incorporated with a capital of $30,000, to manufacture chemicals and chemical byproducts. The incorporators are Glen Snyder, Henry Lake and C. J. Griswold, all of St. Joseph.

THE HERBINE CHEMICAL Co., New York, N. Y., care of Lieberman & Siegel, 51 Chambers St., representative, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are N. M. Goldstein, S. Brown and M. Herbst.

THE NEW JERSEY LEATHER CLOTH Co., Newark, N. J., has been incorporated with a capital of $50,000, to manufacture imitation leather products. The incorporators are Jacob Wallman, L. M. and Fred Scherer, 132 Paris St., Newark.

THE SOUTHWESTERN PRODUCTS Co., St. Louis, Mo., has been incorporated with a capital of $25,000, to manufacture soaps and kindred products. The incorporators are C. B. Brockett, H. W. Jameson and O. M. Charleville, all of St. Louis.

THE FIBRE BOARD & CASE Co., 326 West Madison St., Chicago, Ill., has been incorporated with a capital of $20,000, to manufacture fiber products. The incorporators are Dale S. Johnson, Thomas W. Reilly and Eugene D. Billings.

THE FEATHERED PAINT Co., New York, N. Y., care of L. A. Jackson, 220 West 42nd St., representative, has been incorporated with a capital of $5,000, to manufacture paints, varnishes, etc. The incorporators are H. R. Epstein and A. P. Boyd.

THE LARRY-HINDS Co., 240 Poplar St., Memphis, Tenn., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are W. R. Larry, and M. F. Hinds.

THE HARTEL BRASS & NICKEL WORKS, 270 New York Ave., Union Hill, N. J., has filed notice of organization to manufacture brass, bronze, nickel and other metal products. The company is headed by Otto Hartel.

THE SUPERIOR CHEMICAL PRODUCTS Co., 303 West Chicago Ave., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are Douglas G. and H. J. Logan, and Claude H. Pratt.

THE STERLING ELECTRIC STEEL CASTING Co., Falling Springs Ave., Centerville, Ill., has been chartered under state laws to manufacture steel and other metal castings. The incorporators are Claude L. Harrell and George F. Baker.

THE HAWTHORNE CHEMICAL Co., Hawthorne, N. J., care of George A. McCausland, Hawthorne, representative, has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are William Van Eerde and Jacob C. Bachman, both of Hawthorne.

THE PAYNTER CORP., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $300,000, to manufacture automobile tires and other rubber products.

Industrial Notes

The Pittsburgh Testing Laboratory, Pittsburgh, Pa., announces the appointment of Harry M. Wey, as manager of the Chicago district, with an office located at 1560 Monadnock Block.

The Pennsylvania Pump and Compressor Co., Easton, Pa., announces the recent opening of a district office at 105 West Monroe Street, Chicago, Ill. H. M. Montgomery is in charge.

Samuel P. Sadtler & Son, Inc., consulting and analytical chemists, Philadelphia, Pa., announce that on July 1, Dr. Elbert C. Lathrop severed his connection with the duPont Co. and joined the Sadtler organization as vice-president and treasurer. Dr. Lathrop, a graduate of Depauw University, Indiana, 1907, was for nine years connected with the laboratory of Soil Fertility Investigations of the Bureau of Plant Industry, U. S. Department of Agriculture, where he carried out some very important research on the organic matter of soils for which, incidentally, he was awarded the Longstreth Medal by the Franklin Institute of Philadelphia in 1912.

The Gasoline Recovery Corp. announces that its engineering and sales departments have opened offices at 402 Janet Building, Charleston, W. Va., in charge of E. M. Burdette, vice-president and C. L. Voress, general manager.

The California Master Products Corp., Los Angeles, Cal., producers of white bentonite, calcined magnesite, and other nonmetallic minerals, have just completed an addition to their plant to provide warehouse facilities and allow the installation of a new Raymond 5-roller mill of latest design. F. A. Kaufman is manager.

W. Woodward Williams has been appointed vice-president of the Titan Iron and Steel Co., mechanically puddled wrought iron, Newark, N. J. Mr. Williams graduated from Harvard University in 1905. After six years in the mills of the Carnegie Steel Co. at Pittsburgh, Duquesne and Youngstown, he entered the sales department of the Bowne-Fuller Co., Cleveland, and was later appointed manager of its Pittsburgh office. In January, 1914, he became general manager of sales of the A. M. Byers Co., Pittsburgh, and subsequently was made its general manager. In August, 1919, he became general manager of the Reading Iron Co., and afterward was elected vice-president, in charge of sales and operations. In September, 1920, he became associated with the Pittsburgh Gage & Supply Co., the largest jobber of wrought iron pipe in the United States, resigning the vice-presidency on May 31, 1922, and entering immediately upon his present office of vice-president of the Titan Iron & Steel Co., Inc.

The Wilson Welder & Metals Co., Inc., 132 King Street, New York, N. Y., recently appointed the King-Knight Co., Underwood Building, San Francisco, Cal., exclusive representatives in central and northern California for Wilson plastic-arc welding ma chines and Wilson "Color-Tipt" metals.

The Kelley Island Lime and Transpor Co. has elected John A. Kling of Cleve land, Ohio, chairman of the board an George R. Johnson, of Buffalo, N. Y., presi dent. Other officials elected include: E. W Oglebay, first vice-president, F. A. Beck with, second vice-president; G. J. Whelar third vice-president and general manager F. W. Ohlemacher, fourth vice-presiden and C. A. McMorris, secretary and treas urer with F. W. Kohl as assistant secretar and assistant treasurer.

The Medart Patent Pulley Co., with ger eral offices and works in St. Louis, Mo., ha changed its name to The Medart Company.

Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., announce a numbe of recent changes and transfers affectin several different departments as well a some of the district offices. T. A. McDowe has been appointed executive assistant t the manager of the supply departmen which was recently reorganized. Carl Schluederberg, assistant to manager of th supply department, will hereafter devote a of his time to the foreign supply and mer chandising business. W. C. Koehler ha been appointed to succeed T. A. McDowe as manager of the cost and developmer section. M. H. Scott has been appointe chief clerk of the supply department. Pa H. Smith, manager of the power divisio of the Atlanta office, has resigned to ac cept a position with the Brooklyn Ediso Co. He has been succeeded by Thoma Fuller, who is now manager of both th power and supply divisions of the Atlant office. W. T. Blackwell has been appointe manager of the interior lighting section the merchandising department with hea quarters at South Bend, Ind. A. G. Crocke has been appointed manager of the powe division of the Detroit office and R. Cobban has been made branch manager the Butte office. W. W. Spangler has bee appointed assistant manager of syndicat operations. Important changes have als been made in the power sales departmen The changes include the promotions three managers and the creation of tw new managerships in the Power Depart ment and are effective immediately. L. Bullington, who has been assistant to th manager of the power department for th past several years, has been made assistar manager and will have charge of the ger eral work of the power department. Charl F. Lloyd, formerly manager of the sub station section, has been made manager the electric division and R. E. Carother formerly manager of the turbine sectio has been appointed manager of the steat division. The vacancies caused by the pro motions of Mr. Lloyd and Mr. Carother have been filled by the elevation of Bruc H. Lytle and D. O. Tylee, the former b coming manager of the substation sectio and the latter manager of the turbine se tion.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold summer excursion meeting to Rochester Montreal, Ottawa, Kingston, Toronto, Ham ilton, Niagara Falls and Buffalo, Aug. 13-1

AMERICAN CHEMICAL SOCIETY will hol its fall meeting in Pittsburgh, Pa., Sept. to 9.

AMERICAN ELECTROCHEMICAL SOCIETY wi hold its fall meeting in Montreal, Sept. 2 22 and 23. Headquarters will be at th Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold it annual convention and exhibition at Atlar tic City, Oct. 23 to 28.

AMERICAN INSTITUTE OF MINING AN METALLURGICAL ENGINEERS will hold it 126th meeting at San Francisco, Calif., Sep 25-29, 1922.

AMERICAN SOCIETY FOR STEEL TREATIN will hold its International Steel Expositio and Convention in the General Motor Bldg., Detroit, Mich., Oct. 2 to 7.

ANNUAL SAFETY CONGRESS OF TH NATIONAL SAFETY COUNCIL will be held i Detroit, Mich., Aug. 28-Sept. 2.

NATIONAL EXPOSITION OF CHEMICAL IN DUSTRIES (EIGHTH) will be held in Ne York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AN MECHANICAL ENGINEERING will be held a the Grand Central Palace Dec. 7-13, wit the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY has dis continued meetings for the summer, bu will resume them in October.

THE SOCIETY OF INDUSTRIAL ENGINEER will hold its next national convention an exhibitions of labor-saving equipment a the Hotel McAlpin, New York, Oct. 18, 1 and 20.

Finis to Ford's Offer For Muscle Shoals

COMMITTEES in both houses in Congress have done well to reject Mr. FORD'S offer for Muscle Shoals. The attack was concentrated on his offer of the small sum of $5,000,000 for the nitrate plants and a demand that the power project be leased to him for a term of 100 years. As we have pointed out repeatedly in these columns, these two items of the Ford offer were sufficient to cause its rejection.

It is seldom that a Congressional committee gets as deeply into the details of a technical subject as the Senate Committee on Agriculture and Forestry delved into the intricacies of the Ford plan. The report by Senator NORRIS analyzed the situation in great detail. Not only does he show the impossibility of favoring Mr. FORD with a 100-year lease while other lessees under the federal water power act are limited to 50 years, but he proves quite conclusively that the $5,000,000 offered for the nitrate plants could be recouped almost immediately from the sale of the government's equity in the Gorgas steam plant and of surplus property which was never used and which is not necessary to the operation of the plants. Further, he analyzes the financial phases of FORD'S offer and shows that not only would the government not be reimbursed for the principal sums advanced but would receive less than 3 per cent interest on the money required to complete the great Muscle Shoals power project.

The Ford offer and all others having been rejected, Mr. NORRIS comes forward with a plan of his own which reverts to the original scheme of operation by a government owned and controlled corporation. As we intimated some weeks ago, this completes the cycle of proposals for the disposition of Muscle Shoals and brings us back to the original starting point. Mr. NORRIS proposes that his government corporation shall complete the power project and operate the nitrate plants for the production of fertilizer. He will be sure to meet much opposition from those who object to putting the government into business, despite his plea that it is just as proper for the government to operate power and nitrate plants as it is to maintain battleships and perform all the functions necessary to keep government property in repair. The majority of his own committee is opposed to the measure and it is not likely to receive serious consideration at this session of Congress.

Speaking for the minority of the committee that favors the Ford offer, Senator LADD has prepared a report in which he draws the deadly parallel between the features of FORD'S proposal and Senator NORRIS' plan for government ownership and operation. His principal argument in support of Mr. FORD is that acceptance of his proposal will terminate the heavy expense under which the government now labors in the maintenance of Muscle Shoals and will, in addition, benefit the agricultural industry of the country by industrial research in the production of fertilizers. These advantages, coupled with a vision of the great industrial developments that Mr. FORD will bring about at Muscle Shoals, constitute in the minds of Senator LADD and his colleagues a sufficient reason for letting Mr. FORD have the project on his own terms. Senator LADD sees no reason for quibbling over such details as a 100-year lease and the small price to be paid for the nitrate plants. In short, the burden of the minority report is that the Ford offer should be accepted in spite of its obvious shortcomings because it is the only offer that has been made for the power project and nitrate plants as a whole. Leaving government ownership and operation out of the question, the minority report does not successfully meet the objections to FORD'S plan.

The Seniority Snag In the Railroad Strike

ONE of the unfortunate features of any strike is that the original issues may soon be lost to sight while extraneous matters assume unwonted importance. That is precisely the situation in the railroad strike and is the present cause of practically all the controversy going on among the government, the railway executives and the striking shop crafts.

But if the matter of seniority is extraneous to the original purposes of the strike, it has nevertheless become the one clear-cut issue. It is the one point in the settlement of which a definite principle is involved. The other matters are of a kind subject to compromise, but when the President asks the railway executives to agree that all striking employees shall "be returned to work and to their former positions with seniority and other rights unimpaired" he is asking them to violate a principle on which, in our judgment, there should be no yielding.

Neither the railway executives nor the striking shopmen can come before the public with clean hands as far as their compliance with decisions of the Railroad Labor Board is concerned. Both are guilty of ignoring the authority of this government agency and are justly subject to public censure. But the seniority issue was created by the strikers and not by the executives, and the decision of the executives not to restore the strikers to their jobs with seniority and other rights unimpaired was made for them officially by the Railroad Labor Board. In other words, the successive steps by which restoration with seniority rights has become the principal issue of the strike show clearly that the executives are in a very strong position in refusing to accept the President's proposal. It requires little stretch of the imagination to foresee the consequences

of accepting the government's conditions for calling off the strike. If strikers are to be permitted to disrupt transportation and industry and threaten the welfare of the country and then, after having caused untold inconvenience, loss and damage, return unpunished to their jobs as though coming back from a brief holiday, neither the railway executives nor the Railroad Labor Board nor any other agency will be able to settle future strikes by filling the strikers' places with new workers. If the executives are now required to tear up as a scrap of paper their promises to protect and reward faithful employees and new employees, then they will indeed do violence to every principle involved in the matter and work a gross injustice on the men who made it possible to continue transportation service in spite of the strikers. Regardless of the merits of the original points in controversy, there should be no yielding by the railway executives on the seniority issue.

Quack, Quack!

SCARCELY a week passes without the receipt of printed matter describing some marvelous liquid or powder which will turn merchant bar into finest tool steel, which will double the mileage of a Cadillac if two drops of the stuff are placed in the carburetor, which will convert the purchasable variety of grape juice into extra dry champagne over night, or which will cure warts, corns, sprains, abrasions, cancer and falling hair. Later in the fall we expect to get some more literature advocating the use of some other stuff, "the result of extensive and exhaustive research, experiments, tests and demonstrations by scientists," which will make the mixture of slate and culm to be sold this winter burn like the cleanest anthracite.

That all of these varieties of "Nulife" are sold in large quantity is sure: so many new ones are constantly appearing. And doubtless they are often sold to men who pride themselves with knowing something about their business. A fair share of the purchasers must also be those who have never been victimized before and who must learn from experience, and in no other way, that there is no virtue in nostrums. Furthermore, it is a standing demonstration of the salesman's premise that it is more important to know the psychology of the buyer than anything about his real needs or the nature of the article offered for sale.

Chemical analysis would in most cases show that the largest portion of "Nulife"—and we offer our apology if this pet word meaning all kinds of quack remedies has been previously appropriated—might be water, sand, charcoal, fuel oil or some such cheap ingredient. But not everybody has the opportunity nor the desire for analyzing "Nulife" and finding out whether he could not make it up for himself for about one-tenth the selling price of the "secret composition." Those who have such opportunities ordinarily have wholesome respect for law, and become instantly suspicious of lurid claims, knowing that in the struggle with Mother Nature you can't get something for nothing.

But it would be just as well to spread the word about. There now seems to be a flood of substances on the market by which "wrought iron or bessemer steel of low grade is converted into the equivalent of costly crucible steel as far as physical properties are concerned." A rule-of-thumb or thoughtless heat-treater might easily believe it, remembering the changes he can make in a piece of really high-grade steel by heating and cooling. But he must be warned by more intelligent friends that the metal he has in hand did not appear by merely waving a wand and muttering cabalistic words. It is the result of most extreme care on the part of a hundred men throughout a dozen difficult operations, from the selection of ore and raw materials through steel making, casting, rolling, annealing and inspection. If he will think a little he will agree that all this infinite care, wrapped up in a little piece of flawless metal, cannot be replaced by daubing some dope on some junk and following the printed directions.

Thirty years ago the late Dr. HENRY M. HOWE was encountering these same ideas, and what he said is very much to the point: "You cannot make a bad beefsteak good by the cooking; you can cook it better or worse, and it will be worse or less bad beefsteak, but always bad. On the other hand, you can easily spoil a good beefsteak by bad cooking. Now, just as cooking is to food, so is heat-treatment to steel."

When you dine at LUNG TONG'S chop house in Jaurez, you use a liberal amount of chili sauce and red pepper, and for a very good reason; but at the Waldorf you do not need to drown one of OSCAR'S patties in mustard to make it tasty.

Universities Must Compete With Industry for Leaders

EVERY so often we publish in our personal column a note to the effect that Prof. BLANK has resigned his professorship in the X. Y. Z. University to accept a position in chemical industry. The receipt of another announcement of this kind, soon to be published, was coincident with that of a letter deploring the fact that such a man could not be saved for educational work.

Technical schools must supply trained men to industries and in addition must build up research in the fundmentals of science. This is no mean task. It should enlist the best talent and genius which the country can produce, and yet these announcements continue to come to us of a brilliant young professor entering industrial work. What is wrong? Surely no one will blame the young man, full of enthusiasm, ideas and red blood; eager for the prizes which industry is able to offer. His ambition is the motive power of this country. On the other hand, one cannot blame industry for trying to get men who have developed qualities of scientific leadership.

The problem, then, must be solved in some other way. Young men entering educational work find much that is attractive. The opportunity for real service is a repaying thing. The life, removed from the fret and nag of competition, has charm. The opportunity to do constructive research is appealing. But once the full professorship is attained—and this usually comes early in life—there is no further promotion. No opportunity is presented for achievement comparable to that offered by other professions—law, medicine, even the ministry. What more, then, is needed to keep men of promise and achievement in educational work?

A correspondent who desires to be nameless and for whose opinion we have the highest regard has presented a suggestion which is constructive and sane. He recognizes at once the futility of trying to persuade industry to refrain from tempting such men. Quite rightly he says: "Initiative and leadership are not fostered by neglect and lack of appreciation." He

nedy is to create an incentive to remain in teaching. the prizes be sufficiently alluring to attract the man h initiative and leadership. Compete with industry such men! And the method? Establish a number foundations paying salaries of $25,000 and over—y limited in number so that a comparatively small cent could ever hope to attain the goal. Such prizes uld serve as real incentives to hold men in educa-nal work.

Our correspondent continues by discussing some of restrictions. Such foundations should be reserved men of unusual accomplishment and need not be ed because there happens to be a vacancy. They uld not be pensions and should be held only during productive period. One should be reserved for h of the great fields of educational work—pre-inence in teaching or in research.

This idea is fundamentally sound. Great men appear ere there is great opportunity. If we would keep eat men in educational work we must create great portunity. Nor is this derogatory to the able men eady engaged in educational work. Thank heaven for se that stay, even though their reward is not much tter than that of the vast majority of mediocre men o clog the profession, impart facts and leave the dent lethargic and dispirited. But there is still the ceptional man to provide for, and we suggest that se in authority in our leading universities take the itiative in establishing foundations that will yield laries commensurate with those of industry. Com-tition will get and hold the best men.

mmodity Prices and Business Confidence

T IS rather an interesting point that in the past 10 years we have escaped a "panic" on two or three oc-sions when one was expected. There was rather a despread belief late in 1912 and in the fore part of 13 that a panic was due at about the middle of the ter year. No panic occurred. Perhaps the inception the World War might have been counted on for a nic, but there was none. While it was not the general w, there was a feeling in some quarters that the ling of the war would be followed by rather serious ancial troubles, but we had nothing of the sort.

The experience referred to was not the experience in e previous history of the United States. There had en numerous panics, and they had, of course, been nexpected, for the panic that is seriously expected can rcely happen, because men provide against the con-ion. Individually they set their houses in order.

Remarks are now being made here and there that the undations for a panic are being laid, hope being ex-ssed that things will not really go so far as to make uble. The reference is not to a financial panic, for it now generally accepted that under the Federal Re-ve system a financial or money panic is practically possible. What is thought of is a sort of "buyers' nic," which would cause buyers suddenly to cease ying, thus precipitating industrial depression.

The trends of the times need to be studied carefully, by them one should be able to determine whither are moving. It is a matter of advancing prices, but upward trends in prices are not provocative of panic. e causes and circumstances are to be considered. If rice has been lower than it should be in relation to easonable cost of production with an efficient opera-tion, an advance is healthy. The advance removes ground for doubt and makes the seller prosperous, and prosperity spreads.

One of the tests that may usually be applied is the test of whether the thing that advances is being pro-duced economically and efficiently. That uncovers the cause of the present doubt, the fear that there may be a "buyers' panic." The principal uneasiness at present is due to the fact that some workmen are being paid higher wages than the economic conditions of the coun-try would warrant for all workmen. Furthermore, these workers are not doing a fair day's work. That there are such cases in the building trades is well known. Common labor is being paid approximately 50 cents an hour in some districts. That is too high rela-tive to wages in general, since it would be impossible to establish $1,200 a year—which is what 50 cents an hour amounts to—as a minimum wage, with gradations upward according to the relative value of the services rendered. The wages would exceed the national income —i.e., the goods are not available for spending so much.

It need not necessarily impair the general economic fabric, however, if the high costs are sufficiently limited in extent. If we see many things coming to be produced under disadvantageous conditions, or at unfair cost, we shall then have reason to fear a reaction.

Production Efficiency In the Chemical Industries

EVER since business began to work back to normal conditions following the disruption caused by the war, it has been borne in upon the wise executive that he would best be able to meet competition and conduct his business profitably by giving attention first to the efficiency of his production methods. This fact was emphasized in a most striking manner by a survey of waste elimination conducted by the Federated American Engineering Societies. It has also been stressed less strikingly in the public utterances of business leaders and in the programs of industrial and technical societies.

But what are the factors that influence production efficiency? Waste is but one of them, and while it may have been true that the elimination of waste in all its forms offered many of our industries the quickest route to profitable operation, there are other equally impor-tant elements that must still be given the closest attention if production is to be made on the most effi-cient basis. Some of these factors are mechanical in their nature and some economic, while others fall into the broad classification of human relations. The theme is a large one and obviously cannot be covered in detail short of several large volumes. We shall attempt, how-ever, in our forthcoming Chemical Exposition issue, Aug. 30, to cover the essentials of the subject in a series of articles that have been contributed by recog-nized leaders and specialists. More than a score of topics will be treated, ranging from the mechanical problems of material handling and automatic control, through the economic subjects of cost accounting, the business cycle and problems of administration, to the human elements of the selection and training of work-ers, the preservation of their health and happiness, and their relations with their employers. The issue has been in preparation for several months and we believe its excellence is such as to deserve special commenda-tion, in advance, to our readers.

An Outline of the Uses of Lime

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to D. M. Liddell's further discussion of "An Outline of the Uses of Lime" appearing in the July 19 number of *Chemical & Metallurgical Engineering*, I wish to point out that in writing that article I did not consider lime as being CaO. I believe it is quite generally agreed now that lime is not CaO. A very satisfactory definition for lime is that given by S. V. Peppel, published in Bulletin 4 of the Geological Survey of Ohio, which is as follows: "Lime is the material obtained by the calcination of a stone in which carbonate of calcium is a predominating ingredient." It follows from this definition that a dolomitic limestone calcined either partly or wholly would be considered lime, and that is the sense in which the term was used in the above-mentioned article.

The chemical reaction referred to was that between the magnesium oxide in the lime and the magnesium chloride in solution.

As to the question as to whether or not the use referred to is a use of limestone or lime, I think there could be no question that it is a case of using both. It can be considered a lime product, however, because it can be made from lime by proper chemical treatment.

Should Engineers Be Licensed?

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your invitation for comments on the effect upon chemical engineers of laws requiring engineers to be licensed leads me to point out that many of these laws do not recognize the fundamental difference between much of the work of civil engineers and that of the other major branches of engineering. A large percentage of civil engineers are engaged on public works, either on salary or as consultants, and the apparent purpose of many license laws is to require a proof of fitness of men in responsible positions in such work. With the great mass of mechanical, electrical, chemical and mining engineers, the condition of their work is different, for they are the technical elements of groups having financial, legal, executive and sales elements in order to function properly in meeting legitimate business and industrial conditions. It is the group and not the individual which has become the natural unit in these fields of engineering. For example, a central station company does not go to an individual for information about large turbo-generators, but to the groups, or companies, designing and building them.

The condition that will exist in New Jersey after April 8, 1923, unless the license law is repealed which becomes effective then, serves to illustrate the dangers of license legislation to most engineers. After that date no person may practice or offer to practice professional engineering in that state, unless licensed, for more than 30 days in any calendar year, without incurring danger of being fined $100 to $500 or being imprisoned for not over 3 months or both. "Professiona engineering," the law says, "means the practice of th professional engineer who through technical knowledg gained by education and experience in one or mor branches of that profession initiates, investigates, plan and directs the application of the resources of nature t the use and convenience of man; and who represent himself or herself to be such an engineer through th use of the term engineer with or without qualifyin adjectives, or through the use of some other title imply ing that he or she is an engineer."

There is no provision by which an industrial o engineering company may perform professional er gineering work in the state except upon its ow premises. It cannot give engineering advice in its ow name, representing the combined knowledge and judg ment of its specialists; all the prestige and good wi inherent in that name is wiped out. It must give thi advice in the name of some individual, if at all, whic is plainly contrary to sound public policy and good ec nomics. A few instances will show what the effect o such a law upon the chemical industry will be.

Assume that a gas company in New Jersey wishes t build a large addition to its works and prefers as result of experience to turn the design and constructio over to some company specializing in such work. Unde the law this cannot be done; only individuals can b licensed in New Jersey and there is no provision fo companies practicing through them.

A New Jersey textile mill finds that its dye work must be reconstructed and enlarged. Its plant enginee is able to design the structures and plan the general lay out, but he wishes the help of dye makers and equip ment builders in laying out the details. The only wa these companies can co-operate is in the name of th individuals they delegate, whereas the textile compan wishes the co-operation in name as well as in fact o the employers of these men, as it is company knowledg and guarantees and not individual opinions withou guarantees which it is looking for.

A company having mills in several New Jersey citie finds that the drums of one of its boilers are becomin pitted inside. For years it has referred such trouble to the boiler builder, which has one of its works in th state, where it maintains an organization of engineer and chemists engaged exclusively in studying operatin troubles with boilers. But under the new license law all this valuable information is sealed up and can b utilized, if at all, only by a roundabout process.

The New Jersey license law is the most narrow an inelastic yet passed. It compares with the Pennsylvani law about as sulphuric acid and milk. The Pennsylvani law has been in effect but a short time, yet a suit t test its constitutionality has already been brought When the industries of New Jersey find out what th license law of their state does to them, if it is impar tially enforced and not used merely for oppression o companies out of favor politically, it seems reasonabl to expect a vigorous uprising against such legislation a well as a resort to the courts. JOHN M. GOODELL.

The Proper Status of the Engineering Profession

By R. A. Hart
Senior Drainage Engineer, U. S. Department of Agriculture
In Collaboration With
H. W. Clark and S. A. Roberts*

The Ideals Toward Which Individual Engineers Must Strive if Their Profession Is Ultimately to Take Its Place on the Same High Plane as the Other Professions Are Set Forth and the Shortcomings of the Present Day Engineer Critically Examined

THE STATUS of a profession can be measured only by the standing and standards of the individuals who represent it. The measure, of ecessity, must be composite, with due regard both for ie highest and the lowest factor, but especially for ie mean of the general body of factors.

Were we to measure our profession by its most nowned exponents we could justly feel that a proper atus already has been attained, one not surpassed any other profession. Unfortunately, however, this not proper nor possible and we must regard the atus of such exponents as more or less individual but establishing, none the less, a status that is attainable id must be attained by the profession.

Engineering a Learned Profession

When the proper status is attained the engineering ofession will be truly a learned profession.

This means that engineers will acquire a broad liberal ucation second neither to that of medical men nor the representatives of the bar. Most engineers alize already that the purpose of obtaining an educaon is to enable one to live—not merely to make a ing—to fit one to enjoy the more durable satisfactions life, and that a rigid technical education, however orough and comprehensive, leaves much to be desired. ngineers will be better grounded in the humanities, ey will have a better command of the mother tongue d they will be able the better to express themselves d impress their thoughts upon others whether in all or in large groups. They will know more of e history of mankind, more of the fundamentals of litical economy, of sociology and of psychology, for ey will realize more fully than now that engineering s to do not only with material resources and sources power but with man himself, both as a factor in proction and as the fundamental motive of inspiration r the whole engineering process.

Needless to say, the purely technical education will t be neglected in the search for broader culture. deed, the scientific and technical phase will be insified, but at the same time broadened. Due to the pid evolution of the profession in America during e past half century, the educational system has been mpelled to readjust itself from time to time, being ayed first in one direction by a doctrine of practical ining that would have made a trade school of the llege, then in the other direction by a doctrine of ltural development that would have ignored the ilitarian aspect to a harmful degree. Our present stem is a compromise that provides for too much ecialization on the part of the engineering student. e engineering undergraduate education of the future ll provide for a more thorough grounding in the ndamentals of science and of engineering unmodified adjectives. Specialization will await the period of post-graduate study or the development under conditions of actual practice. Newly-fledged engineers, unless they have had the wisdom to interpolate practical experience between their years of technical study, will be of less value to employers for a period, but eventually they will be worth more to employers or clients, to civilization and to themselves.

Finally, the engineer of the future will reach a higher aesthetic development. He will come to appreciate and enjoy the finer things of life and he will not feel out of place in association with those whose lives touch these things more intimately.

When the proper status is attained, engineering will be recognized as a learned profession by engineers themselves, by the members of the other learned professions, by the law, and by laymen generally.

It has been but two generations since engineers were generally regarded as nothing more than high-grade mechanics. Engineers did not take particular exception to this classification and even today there are engineers whose perspectives do not define a higher status. Such engineers, admittedly, constitute a small minority, but there is a much larger proportion of the membership of the profession whose attitude toward culture in general, particularly toward the necessity for a proper regard for accuracy, effectiveness and clarity, not to say beauty, in the spoken and written word, constitutes a depressing factor in the struggle to advance the status of the profession. Many engineers have no more realization of the seriousness of their deficiencies in liberal education at the close of their college careers than they had of the desirability of such education at the beginning of their technical education, and as a consequence make no attempt to correct the deficiencies by personal effort after entering practice. Many others, realizing their deficiencies, conclude that it is too late to apply a remedy. Most engineers sincerely believe that their professional work leaves no time for perusal of anything but technical matter, newspapers and general periodicals; others find no time even to continue their technical development save through experience.

Recognition Must Be Sought

It may be said that the engineering profession has already been admitted to the honored company of the learned professions by the consent and acknowledgment of the membership thereof. It is realized that an engineer must have had a training equivalent to that of a doctor or a lawyer, for example, and that the nature of his subject matter is such as to require commensurate mental equipment, but the impression is firm that the training is special, highly technical and narrow and the recognition of the profession as a learned profession involves a mental reservation. One of our goals must be to eliminate this reservation.

From the legal standpoint, the engineer has been in a peculiar position. He has had the protection neither of the mechanics or material man's lien, with respect

*Messrs. Hart, Clark and Roberts were members of a committee the Engineering Council of Utah which prepared this article.

to remuneration for services rendered, nor that afforded to the members of most of the other professions through examinations for the bar, license laws and certification. The engineer has occupied a twilight zone in which he has been left at the mercy of his employer or client on the one hand and of the pseudo-engineer on the other. When the proper status is attained the engineer will have ample legal protection.

In America particularly, the laity has not accorded the profession the rank acknowledged even by the other professions and great effort must be expended before the proper recognition is secured. In France, the engineer is a gentleman and a scholar and is recognized as such. In England the engineer is frequently of the aristocracy. Even in Mexico there is no possibility of confusing the engineer with the driver of a locomotive as the one is called *inginerio* and the other *maquinista.* When the proper status is attained the layman will distinguish the engineer from the engine-driver, he will discover in the civil engineer more than the runner of lines and the driver of stakes; he will requisition the services of the engineer more and more, and he will retain the engineer on the basis of ability and service, not on the false basis of relative price. He will come to recognize the time element as non-essential and that the element of service or of opinion is paramount.

Development of a High Professional Sense

When the proper status of the engineering profession is attained it will be found that engineers generally have developed a high professional sense controlling their individual relations with the public, their individual relations with each other and their collective activities.

Engineering is essentially honest. It deals with immutable laws and the engineer discovers very early in his career that he cannot go counter to these laws and succeed. Whatever his natural inclination may be, he gets into honest habits. By the time he reaches the status where his opinion rather than his services is in demand, he has developed a very jealous regard for his reputation and this serves as a further protection. He finds that he is a dispenser of justice. He is not an advocate for either party in a controversy but his duty it is to expose the truth. It appears that engineers in general have come nearer attaining the proper status in this than in any other phase of the question. It is not to be denied, however, that there are men in the profession who fail to rise to the standard now established—men who will sell a favorable opinion for a fee; men who will advocate a wrong cause; men who will permit their judgments to be warped for a consideration or, perhaps, by insidious suggestion.

Curiously enough, while engineers in general have established a very high standard with respect to their fiduciary relationship, the same high professional sense does not apply to their relations one with another. This is largely due to the fact that engineers are more or less individualistic and the rapid economic development, particularly in America, has resulted in a keen competition in achievement which was worthy and beneficent but which, under conditions of stress evolved into a keen competition for work to do, and this latter competition has produced some very unworthy aspects. This is, no doubt, a passing phase and in the interest of the advancement of the status of the profession it should be firmly kept in mind that every injury done by word or act to a member of the profession is an injury to the profession and therefore to the instigator himself. The first electrical engineer said, "We must all hang together or assuredly we shall all hang separately."

The ethics of the engineering profession as yet are unwritten and this may be the reason why they are often ignored by engineers in their dealings one with another. Whether or not it is a reason, it is not an excuse, since there is a written code of ethics, available to every engineer, that covers the situation. The code comprises only eighteen words and may easily be memorized. It is as follows: "Therefore all things whatsoever ye would that men should do to you, do ye even so to them."

Engineers are beginning to act collectively. If the proper status of the profession is to be attained speedily such collective activity must be on a high plane. There must be nothing that savors of trade unionism. Every endeavor to advance the status of the profession must be of the highest order. Engineers must adopt an absolutely unbiased attitude with respect to the adjustment of the differences between capital and labor. In the matter of the promotion of legislation, engineers must operate with an eye single to the good of all and not serve one class or interest to the detriment of another.

When engineering attains the proper status there will be more business in engineering and more engineering in business. It is said, perhaps justly, that engineers do not possess a high commercial sense; indeed, many lack even the element of good common sense. Commercialism is distasteful to most engineers. This is not an uncommon characteristic of professional men generally, but with engineers particularly it is essential that economics shall have a full measure of regard. Engineers are notoriously poor salesmen, even of their own services. If engineers are to measure up to their opportunities they must develop the commercial instinct to an extent where they can sell ideas in the first place and then properly direct the application of the idea to the end that the product shall fill an economic want in an economical manner. Engineers must come to realize that the most effective instrument of engineering is the almighty dollar and that it is fully as essential to know the powers, purposes and limitations of this instrument and how to use it effectively and efficiently as that of any other or all other instruments of the profession.

Broader Power and Authority Involved

It seems almost unnecessary to say that the men in this world who are doing the things should have most to say about *what* is to be done, *when* it is to be done and *how* it is to be done. The fact remains, however, that engineers do not have a sufficiently effective voice in these matters. Generally the broader plans are laid, the organizations are effected, the policies adopted, the ends to be attained decided and perhaps even the financing arranged before the engineer is called upon to produce results. Somehow, handicapped and circumscribed as he is, he generally produces the result. How much better would it be for all were the engineer to play an important if not dominant part in the general plans and their collateral phases.

Great administrators have come to lean very heavily on their engineers and this is gratifying so far as it goes, but the question naturally arises, Why should the organization be such that the head must lean on the

lieutenant? Evidently the engineer is able not only to stand alone but to bear up under the weight of his chief. If the engineer suffers a deficiency that justly condemns him to the secondary position, let him correct that deficiency and the whole organization will profit by the readjustment.

But while great administrators have had the wisdom to lean heavily upon their engineers it may be said, in general, that administrators of smaller caliber and boards of directors generally fail to do so. They are more inclined to lean upon their attorneys for counsel in matters of administration and finance. This is entirely proper to the extent of the legal aspects, but when it comes to the more or less practical aspects it is unfair to the attorney to require his advice, as he is unfitted usually, both by temperament and training, to give the most competent guidance and his legal reputation itself may suffer without warrant in the event of his practical adhortation being erroneous.

The accountant and the banker come in for a due share of consideration by administrators and boards of directors in matters of administration and finance, but here again there is a tendency to fail to recognize limitations. The good banker is the conservative banker. For him to lead would be fatal to the financial structure. He must go only so far as he is compelled. He is the governor on the engine of material progress, not the actuating power. The accountant deals with things as they are and it is his duty rather to proscribe than to initiate. The attorney has his being in precedent. He deals with a system of rules of action that are but the crystallization of public opinion. Crystallization involves a time element and it follows naturally that the law ever lags and never leads in the progress of the race. The attorney must ever look backward and yet backward. His thinking is *a posteriori* in consequence.

The engineer by nature and training and experience is fitted best to bring in the element of vision so necessary to progress. Progressive by nature, grounded in the immutable laws of science, experienced in their practical adaptation and application, possessed of a constructive imagination, gifted with a sense of values and proportions, trained in *a priori* reasoning, urged on by the highest traditions of his profession and blessed with a reasonable assurance, the engineer is destined to lead humanity in its upward and onward progression.

Activity in Public Affairs

When the engineering profession attains the proper status, engineers in general will play a more important rôle in the drama of public affairs. There will be an increased voluntary activity and there will be a greater call to service.

It is said that most engineers do not bother even to vote. Certainly they are much less active in political matters than is excusable. It is the exception to find an engineer rendering his voluntary service in a strictly public capacity. He prefers to be a doer and to leave the talking to those who cannot do. Experience has shown this to be disastrous both to the engineers and to society. Some of the reasons for this aversion have been referred to. They will disappear with broader culture. There is an element of inertia involved, however and this must be overcome by individual and collective effort.

The voluntary intensified activity will be accompanied by a call to service on boards, commissions and in governmental affairs generally. It will become a custom if not a law that at least one member of every board or commission touching the public in any practical manner will be an engineer and that boards and commissions having to do with engineering matters strictly will be composed of engineers. The spectacle of the highway commission of a great commonwealth, a commission dealing entirely with engineering problems in the broadest sense, being made up of non-engineers will not be witnessed.

The minds and talents of engineers will be brought to bear upon the solution of the perplexing problems of civilization that have so far defied the best efforts of politicians, legislators and statesmen and if past performance by engineers in other matters be employed as a safe guide, we may confidently expect the same satisfactory results.

Compensation

The compensation of the engineer is twofold and is both direct and indirect. The direct compensation is the satisfaction which comes to him from doing something worth while and from successful accomplishment. Such compensation is limited only by the degree of his enthusiasm in his work, by the sincerity of his desire for rendering service and by the integrity of his application to his task. Thus the control is largely in his own hands.

But the engineer is one of those happy mortals who receive pay for doing what they like to do. Such pay constitutes the indirect compensation of the engineer and it is essential that it be sufficient in amount so that the engineer may live a well-rounded life in order to continue his service to mankind. It is this indirect compensation to which we refer when we say that the engineer is undercompensated. When the proper status of the profession is attained there will be no criticism to offer on the score of compensation.

A consideration of proper compensation for engineers involves a question of nature as well as of amount. A young engineer is valuable particularly for his services and there is some justification for the employment of a time basis in connection with compensation. The mature engineer, on the other hand, is valuable largely for his opinion based on experience and his judgment, which involves mental quality and caliber. In neither of these does the time element function. A right opinion is valuable regardless of whether it is rendered instantaneously or as a result of much calculation and consideration.

The time unit serves fairly well for the activities that involve manual operations. It fails utterly in the case of the service rendered by mature engineers. The value of the service rendered is the only satisfactory measure of his compensation. Many examples might be given to illustrate the fact that a good engineer saves at least the cost of his fee on each project.

Effort should be directed more toward a change in the nature and the basis for engineering compensation than toward advance in rates and classification. The one goes hand in hand with the whole movement to advance the status of the profession, while the other runs counter to it and may operate to its detriment. Proper compensation will follow as a matter of course when the proper status has been attained.

Summing up then, it has been shown that when the proper status of the engineering profession has been

attained, the profession will be truly a learned profession and universally will be recognized as such. Engineers will acquire a broader culture and a higher refinement. Their undergraduate scientific training will be broader and specialization will await the postgraduate period. Engineers will have a better legal status than now and they will develop a higher professional sense in connection with their individual relations with the public, their individual relations one with another and their collective activities. They will find it necessary to develop a higher commercial sense and to become much more active in public matters. The question of compensation will adjust itself to the status.

Determination of Gases in Metals

By Harold Lester Simons

(Contribution from the laboratories of the Magna Metal Corporation.)

A VERY common source of trouble in metallurgical work is that the resultant product is "gassy." Naturally, before any remedy may be applied, it is necessary to know just what gas is causing the trouble; and, furthermore, it is desirable to be able to ascertain the nature and quantity of gas in any given sample of material in order to determine the efficacy of the treatment resorted to in an attempt to remove it.

It is obvious that even under the best of conditions for analysis (and correspondingly worst condition of material) the amount of gas present must be very small indeed—a fact which any proposed method must take into account.

Hempel[1] advocates the use of a hollow mercury-filled drill in which the gas is collected. This procedure has the objection that a small amount of air is always obtained with the gas sought, this being likely to result in some confusion. Furthermore, although cast iron does not amalgamate with mercury, most other metals do. This will obviously render the procedure difficult.

Ryder[2] has evolved a method which is apparently an excellent one; but it involves employing the metal in filament form and is, therefore, unsuitable if the original material is in somewhat large pieces.

The fact that mercury does amalgamate with most metals suggests that, by means of a somewhat large quantity thereof, a solution of the metal in question may be formed and the liberated gas pumped off. Accordingly, the apparatus illustrated diagramatically in the accompanying figure was constructed and has been employed most usefully in connection with work in this laboratory.

A is a 200-c.c. round-bottom pyrex flask with walls about 1 to 1.5 mm. thick and top flared. The flare is used as a mercury seal where it makes joint with a ground-in stopper of ordinary soft glass. *B* is a tube which slants downward and meets the stopcock *C*. (Incidentally, all stopcocks and joints are mercury sealed.) *D* is made of capillary tubing which extends almost to the bottom of flask *E*, which is filled with purified mercury which has been boiled for some time in order to free the flask from air. *F* is a water-cooled condenser which may, however, be replaced by a long glass tube if desired. *G* is another mercury-sealed stopcock and *J* is a Geissler tube for spectral examination of the gas. It is connected to the apparatus by a bent and bulbed tube in order to catch any stray drops of

[1] "Methods of Gas Analysis," by Hempel (trans. by Dennis) (1912), p. 18 ff.

[2] *J. Am. Chem. Soc.*, vol. 40, p. 1656 (1918).

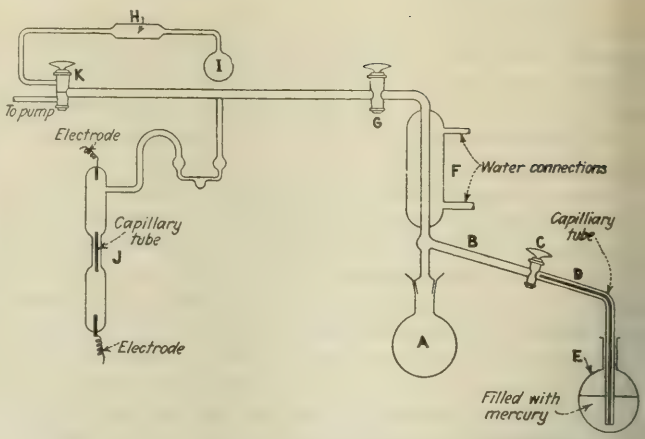

FIG. 1—SKETCH OF APPARATUS FOR RECOVERING GAS FROM METAL

mercury. *K* is a two-way mercury-sealed stopcock which leads on the one hand to a Toeppler pump and on the other to *I* (a source of pure oxygen), which is a bulb filled with pure potassium permanganate covered with glass wool. *H* is merely another bulb filled with phosphorus pentoxide to dry the oxygen.

In practice the apparatus is flooded with pure dry oxygen (obtained by heating *I*) and exhausted by means of the pump. *C* is then opened very slowly and mercury permitted to rise until it reaches the middle of tube *B*. Dry oxygen is then admitted to the system, after which *A* is removed and the metal samples inserted. As much as 75 g. of certain high-magnesium alloys in pieces about 2 x ½ in. have been used.

A is again fastened on and mercury placed in the seal. The complete system is now evacuated to about 1 mm., when it is again flooded with oxygen. The pumping is now continued until a spark refuses to pass in *J*, save with the greatest difficulty. Even then no spectral lines should be observable. It may be remarked in this connection that hydrogen (and nitrogen) lines are rather persistent and serve as a good criterion of complete evacuation. Since the current from an induction coil is not a pure sine function, one electrode of the Geissler tube remains colder than the other and retains more adsorbed gas. Therefore it is best to reverse the electrical connections frequently.

Stopcock *G* is now closed and mercury permitted to run in slowly by opening *C*. The rate at which this is done will depend upon the metal under examination. It is desirable to warm the flask with a bunsen flame. If the metal dissolves with difficulty or is present in large quantity, flask *A* is filled about two-thirds with mercury and stopcock *C* closed. The temperature may now be readily raised to the boiling point of mercury under atmospheric pressure. This elevated temperature greatly facilitates solution.

The flask and its contents are now permitted to become fairly cool before proceeding further—for if this is not done, the mercury will vaporize so rapidly that it will condense in all parts of the apparatus. Now open stopcock *G* slightly (*C* and *K* must be closed) and then shut it. Examine the gases spectrally at this time. A glass tube of about 25 c.c. capacity with stopcock at its upper end is now placed over the mercury sealed exit tube of the Toeppler pump. The tube and stopcock are completely filled with mercury by suction and supported in this position.

Everything is now in readiness to collect the gas by operating the pump after making connection through

It is well to examine the gas spectrally at inter-ls in order to note any change in its nature. This amination also serves to detect a leak. Gentle boil-g serves to render easy the liberation of the entire antity of the gas, which after collection can be ex-nined by the ordinary methods of gas analysis.

As the work performed at this laboratory is of a ry specialized nature, no advantage would be had by blishing results of isolated analyses. Many tests have dicated, however, that consistent results can be ob-ined by the method. For instance, a certain high-agnesium alloy, purposely made rather gassy, con-ined 0.083 c.c. gas per gram, which proved to be actically pure hydrogen by chemical analysis, although e spectroscope showed a trace of argon. Duplicate mples showed substantial agreement.

The author wishes to express his gratitude to Prof. ston Stevenson of the College of the City of New ork for his invaluable assistance and for the use of ivate apparatus in carrying out this procedure.

He also desires to extend his thanks to Andrew C. icksen of these laboratories for his most valuable sistance in parts of this work.

Paper From Southern Spruce-Pine

EXPERIMENTS recently conducted with the variety of wood known in the South as Southern spruce-pine e said to have demonstrated the value of the timber as pulp wood for paper manufacture. Exhaustive sur-ys are now being conducted to determine the amount timber available for newsprint manufacture and ans are being prepared for the erection of a paper ll on the Warrior River in Alabama, near Birming-m.

There are hundreds of square miles of the spruce-pine vering the hills and ridges throughout the northern d northwestern section of Alabama. The trees grow ong the banks of the river down to the water's edge, d stretch for miles along the banks of the stream. is estimated that there is enough timber standing supply one or more large paper mills for 100 years. is said that the trees reach the proper size for paper-aking in about eighteen years. The trees grow to considerable height; there is almost a total absence of art and only a trace of rosin. The fiber is almost entical with that of Canadian spruce and a cord of e Alabama wood makes a ton of paper pulp, the yield ing the same as with the ordinary spruce.

The proximity of the pine forests to the Warrior ver means easy, quick and cheap transportation of e logs to the proposed mill, as well as a 20 per cent ving in freight to purchasers of the finished paper, e to the fact that the combination water-rail freight te is considerably less than the all-rail rate. Experts clare that the wood can be delivered to the river at e-fourth the cost of delivering logs from the Canadian rests to the Northern paper mills.

The Southern spruce-pine has heretofore been con-dered a worthless product. Unfit for lumber and of fibrous nature, it decays quickly and has found no actical use in the South. The foliage is very short d contains many cones. The bark is unusually thin, d of much lighter color than that of the regular llow pine used for lumber. The trees grow only on e hills and knolls, being rarely found in the valley southern Alabama nor where there is a surplus of isture. Preliminary surveys indicate that the yield

CROSS-SECTION OF MATURE LOG OF SOUTHERN SPRUCE-PINE

in the territory along the Warrior River will average from 10 to 20 cords per acre. It is believed that the present supply is sufficient to last a fair-sized mill for fifty years, but in view of the rapid growth of this species of tree the supply might be said to be practically inexhaustible. An interesting experiment to demonstrate the practicability of using this species of spruce for newsprint was recently conducted by the publishers of the Birmingham *Age-Herald*. A recent issue of this paper was printed entirely on stock manufactured from the Alabama wood. The timber was cut along the Warrior River, shipped to Niagara Falls and converted into print. The report from the mill which handled the wood was to the effect that it grinds as easily and has as good fiber as Canadian spruce.

The weight of the paper is 32 lb., and the breaking strength 11 lb. per square inch, thus conforming with standard specifications for newsprint.

Electric Pig Iron in Sweden

The Engineer for July 7, 1922, contains an unsigned article on "Electric Smelting of Pig Iron in Sweden," commenting on a late test of a pig-iron furnace of the conventional type. The furnace has a height of 13.7 m. over all, 38 cu.m. capacity, and produces 23 tons of pig iron per day. In the official test, one metric ton of pig required 1,749 kw.-hr. (theoretical 1,301; efficiency therefore being 74.4 per cent). Magnetic ore containing 67.3 per cent iron was used, P 0.006 and S 0.004.

It is pointed out that the exceptional purity of the Swedish ores (the average of the whole country's reserves is 60 per cent Fe) and the resulting slag volume (15 per cent of the iron produced) are great factors leading to the success of electric smelting. If the charge contains any considerable amount of sulphur, the sulphur in the pig iron is regulated with extreme difficulty —it varies with the temperature of the hearth and returns to normal very slowly. Another controlling factor is the cost of electric power and charcoal versus coke.

Quality Control in Cement Manufacture*

By Richard K. Meade
Consulting Engineer, Baltimore, Md.

An Analysis of the Crucial Points of Portland Cement Manufacture and a Discussion of the Kind of Control Necessary at These Points to Produce Cement of High Quality

CONTRARY to the general belief, the question of the quality of cement is more often a mechanical than a chemical problem, or rather perhaps one of the relation of the mechanics of the process to the chemical composition of the product. The connection between the chemical composition of cement and its physical properties is now so well understood that there are few instances where the poor quality of the cement is due to a lack of knowledge of what the chemical composition of this should be. Generally speaking, poor quality is due to circumstances which interfere with the attainment of the ideal composition by the chemist. In speaking of composition in this paper the term is not limited to the mere analysis of the cement, but includes the proper combination of the elements to form the so-called cement clinker.

Problems of Manufacturing Good Clinker

The problem of manufacturing good clinker in laboratory quantities is extremely simple. It is merely necessary to grind finely a properly proportioned mixture of argillaceous and calcareous substances and then to ignite the mixture to the point of incipient vitrification for a sufficient time to allow proper chemical combination of the elements composing the mix. All the details of the process are well understood by cement chemists—the proper relation to be had between the argillaceous and calcareous elements, the fineness necessary to secure intimate contact and the degree of burning to promote combination are all matters of common knowledge in the industry. When it comes to handling large quantities of natural materials and to manufacturing cement economically, however, the problem is vastly complicated. To begin with the raw materials, these generally vary considerably in chemical composition in different parts of the deposit and the method of accurately sampling and proportioning these materials is one of the most troublesome problems with which the cement manufacturer has to contend. The question of the degree of grinding is generally limited by the mechanical equipment provided and is always influenced by the question of economy. The problem of burning is much simpler than the other two and is usually merely one of securing experienced and conscientious kiln attendants.

These three primary operations of cement manufacture bear a general relation to each other. Some years ago the writer called attention to the fact that, assuming the chemical composition to be correct, there is a very definite relation between the fineness of the materials, the temperature of burning and the time at which the materials are subjected to this temperature. This relation can be best illustrated by means of a mathematical formula thus

$$F \times D \times T = C$$

In which F represents the fineness, D the temperature, T the time, and C clinker (a constant quantity). It will be seen that if C is a fixed quantity the others can vary among themselves and still equal C. Thus with a coarsely ground mixture, the time or temperature of burning, one or possibly both, must be increased to secure proper combination. Similarly if the time in the kiln is short this must be made up for by higher temperature or finer grinding.

If the fact that the composition of the mixture of argillaceous and calcareous substance can vary is considered, another variable is added to the equation. It is, of course, well known that it is much easier to burn low-lime cement than high-lime cement, in which case coarser grinding satisfies. In actual practice, the details of cement manufacture, therefore, are a general compromise to suit local conditions between chemical composition, fineness of grinding and degree of burning.

Fine grinding and harder burning as indicated above will tend to correct faulty composition in some instances. The importance of fine grinding of the raw materials and of proper burning are, of course, better understood and when these are the cause of poor quality the remedy is evident.

Absolute Chemical Control Necessary

My own experience indicates that the problem of making cement of uniform high quality is largely one of *absolute* control of the chemical composition of the mixture fed to the kilns. Occasionally the raw grinding or burning equipment is insufficient, but for the most part the failure to control the chemical composition of the mix has been responsible for the irregular quality of the product.

Chemical analysis of the cement does not always show the trouble, particularly when this analysis is confined to a sample representing a large quantity of cement, such as a bin of several thousand barrels or a day's run—because such a bin of cement may be the average of several hours of very high-limed and consequently unsound cement mixed with several hours of low-limed cement; the average of the two being often near the desired chemical composition but the physical properties of the resulting cement retaining something of the undesirable characteristics of both the high-limed and low-limed clinker.

Such a result is quite apt to occur in the dry process where chemical control is generally a matter of examination of a mixture already made rather than of two materials about to be mixed. It is, of course, well known to most cement manufacturers that the routine tests of the dry-mill laboratory are post mortems rather than diagnoses. They are of no value so far as correcting the composition of the particular lot of raw material under examination is concerned, but serve as a guide to the making of succeeding lots.

By far the larger number of mills, both wet and dry make their mix by means of what are, in the vernacular

*Paper read before the Portland Cement Association at Atlantic City, June 27, 1922.

the industry, known as "readings." That is, samples the mix are drawn from the grinding mills at stated tervals of time and in these samples the carbonate of me is determined. If this is found to vary from the sired standard, no correction can as a rule be made that portion of the mix which has already been pre-ared, and the test serves principally as a guide to the roportioning of succeeding lots, etc. When the mix is ntrolled by such a process, the chemist finding his ixture too high or too low in lime (as shown by the ading) decreases or increases his limestone to cor-ct his proportions. In the dry process this often has ie effect of sending his composition to the opposite xtreme, with the result that while his low-lime and igh-lime clinker will average properly very little of it *per se* of correct composition.

In the wet process, however, an opportunity is gen-rally given to mix the whole lot of ground material y combining the contents of several slurry basins in ie large kiln feed basin and in this way the averaging done before the kiln is reached and hence the clinker of correct composition.

At many dry-process cement plants, the question of hemical control is largely one of good judgment on ie part of the chemist rather than of chemical test. or example, let us cite the case where a limestone and hale plant is supplied with rock by one large steam hovel. The shale is regular but the various strata of mestone differ much in chemical composition. Added o this variation is also the fact that 3 or 4 ft. of clay verlying the limestone is not stripped from the latter ut is blasted down with it. Deep well drills are used nd the shots are large, each representing several nonths' supply of stone. All stone is sent direct from ie shovel through crushers into a relatively small torage bin and the mix is controlled entirely by "read-ngs" taken from the tube mill discharge. Let us sup-ose, as frequently happens, the shovel is working in ie morning on clean limestone comparatively free from tripping. At noon, it encounters a limestone mixed vith stripping and by night it has worked through the tripping and is back on the clean stone. What happens o the mix is this: Some time during the afternoon the ample drawn from the tube mill shows the mix to be verclayed and the chemist accordingly decreases the hale. The orders to make this change probably reach he raw mill about the time the shovel reaches clean tone again with the result that the next sample drawn rom the tube mill will show the mix over-limed. At his mill, the mix would generally be wrong but for the isual inspection and good judgment of the chemist. This condition is by no means unusual and while prob-bly not existing often in such exaggerated form, does ccur in a more or less modified form at many mills.

Superiority of American Cement Evident

In my opinion, it is everlastingly to the credit of the American cement chemist that he can make cement *uperior* to any in the world with the crude methods ften supplied him. He may not be as "long" on theory s his English and German confrères, but for the exer-ise of good, hard common sense and rare judgment he as them both, to use a slang expression, "backed off he map."

So far as quarrying methods are concerned, the steam hovel and the deep-well drill are likely to stay, and it s also in most instances more economical to include the verburden in the blast rather than to strip. At the same time, it is evident that these three improvements in quarry efficiency have increased materially in most instances the difficulty of securing a uniform mix. The big blast throws down the entire vertical face of the quarry in one jumbled heap. If it served also to mix the various beds intimately it would be of advantage. Unfortunately the opposite is generally true and the beds remain almost as separate, but not as easily segregated after the stone is blasted down as when in the position left by nature. In the case of the old method of quarrying by means of 16- to 20-ft. benches, the beds were usually blasted down in some sort of order and could be quarried uniformly. The steam shovels also confine the stone supplied the mill to that obtainable from one or two points in the quarry, while with hand loading the stone can be obtained from almost the entire area of the quarry.

Lack of Uniform Overburden Presents Problem

If the overburden could be intimately mixed with the stone there would generally be no objection to its being blasted down with the stone. Unfortunately this result cannot often be obtained and the overburden usually lies over part of the rock only.

With these new conditions occurring in the quarry, provision must be made at the mill to take care of the irregular supply of stone and clay sent to the mill by the shovels. The influence of occasional variations in the composition of the raw materials are designed to be taken care of at most plants by storage bins of varying forms and sizes.

Usually the shale or clay supplied the mill, whether obtained by means of shovels or hand labor, is of regular composition. Sometimes with clay the moisture content needs careful supervision. A few mills use a calcareous shale in which the lime content varies over quite a range. The use of such shale always greatly complicates the problem of controlling the chemical composition of the mix by introducing two variables instead of one.

Storage of Stone and Prevention of Segregation

The employment of a large stone storage divided into two or more bins seems to be the most feasible method of securing a uniform raw material. In many instances, however, such stone-houses are poorly designed. If we place rock continuously on the middle of a pile and draw at the same time below from the center of this, we will obtain pretty much the same stone that is being delivered to the pile and very little if any mixing will occur. Even where the discharge is not directly under the point of filling this flow of material between the two points occurs. In designing a stone-house, therefore, this should be divided into at least two bins, although it is doubtful if anything is gained by numerous small tanks or bins.

Another action which should be kept in mind is the so-called segregation of materials in the bins. If a mixture of coarsely crushed limestone is fed from an overhead source into the center of a pile it will be found that the coarse material will roll to the outside of the pile while the fine material will lie where it falls. If the pile is tapped from the center, the first material drawn is almost entirely the fines while the coarse material is the last to be obtained. As the fine material usually contains the stripping and is always lower in lime than the coarse material, it will be seen that the composition of the material obtained when the pile is first tapped

will be much lower in lime than that of the last portion obtained.

Many plants employ what are termed blending bins, consisting of large tanks in which the coarsely crushed material is stored. My observation has been that these bins instead of blending, actually segregate, for the reason given above.

It has always seemed to me that the traveling crane and grab bucket afford excellent methods of storing limestone. With this outfit the material as crushed can be uniformly distributed over a large pile. There is no segregation of fines and coarse and the reclaiming can also be distributed over a large area. It is a simple matter for the chemist to work out for the crane operator a cycle of filling and emptying such a storage which will give uniform material and leave nothing to the judgment of the operator.

Another excellent storage is one consisting of several long rectangular and fairly deep bins filled by means of an overhead belt conveyor. This latter is in turn equipped with a traveling tripper. This tripper is so designed as to move at a regular rate slowly back and forth over the entire length of the bin and spread the material in uniform layers over this. If the bin is relatively narrow and the openings below are alternately to each side of the center line, the segregation between coarse and fine material is negligible where the stone is drawn from several openings.

For those who prefer a pan conveyor or bucket carrier to the belt conveyor, the buckets can be arranged to deposit the material at a number of points in the bin. No doubt, other methods of securing the same result are available. Where a silo storage is employed, if the number of bins is sufficient to permit it, better results will be obtained by filling or emptying a number of these at the same time by some such method as I have suggested, rather than to fill and empty in rotation.

So much for the form of storage. Another fact which should be borne in mind is that the finer the rock is crushed the better mixture will be obtained and the less segregation will occur in the bins. For this reason, I would suggest crushing the materials as far as practicable before storage.

Proportioning the Mix—Sampling and Measuring

For determining the proportions of the two materials where the mixing is done directly after the large stone-house, two methods are generally employed. One is to obtain a sample of the contents of the bins of clay and limestone and mix the two as indicated by the analysis of this sample. The other is what is generally designated as the "reading" method and consists in mixing the two materials according to the results obtained from a determination of the carbonate of lime in the mix after this has been ground in the mill. In spite of the fact that it is apparently much the less scientific of the two methods, the second one will usually give better results. This is because of the difficulty of properly sampling material in large pieces mixed with fines and intermediates.

The only method of sampling such material which will give accurate results will be some system of crushing and quartering in several steps such as is used for ore sampling and this would involve an expensive sampling plant. As an illustration of such a plant, let us suppose that the material came from the crusher in a pan conveyor. Arrangement could be made to trip every tenth bucket into a small crusher which would crush to, say, 1 in. and under. The discharge from this crushe would then be sampled and the sample crushed to, say ½ in. This ¼-in. material in turn would be sampled an the sample crushed to 10 mesh. The fine material coul then be sampled and this final sample ground to th necessary fineness for analysis. It will be seen tha such an arrangement would involve handling quite a lo of material.

In a cement plant using 1,000 tons of stone per da the first sample would amount to 100 tons to be crushe to 1 in., the second to 10 tons to be crushed to ¼ in., th third to 1 ton to be ground to 10 mesh and the fourt to 200 lb. to be ground to laboratory fineness. It i doubtful if accurate results can be obtained with muc greater fractions. It will readily be seen that th equipment necessary for such quantities is beyond tha now available in cement mill laboratories.

The methods necessary for securing uniform rock a the mill are the same whether the wet or dry proces is employed and the desirability of such a supply o rock of uniform composition is as great in the on process as the other. In the older wet process plant provision was made for adding clay or marl as desire to the ground slurry before this was pumped to th kiln supply basins. Today, however, when necessary t correct the composition of the slurry, the general prac tice is to mix two or more tanks to give the desire results, so that as far as the mix goes, the two processe approach each other much more nearly than they di when the raw materials of the wet process were ma and clay. In the matter of chemical control, there ar unquestionably much better facilities provided at mos wet-process plants than there are in the general run o dry-process mills. When difficulties of controlling th mix to occur in wet-process plants, this is usually du to too few or too small slurry basins and kiln fee tanks or to improper or insufficient agitation.

Dry-Process Plants Need More Complete Contro

The writer has always felt that the methods employe to control the mix at most dry-process plants are in sufficient and that a system of correcting tanks planne after those of wet-process plants could be employed t advantage. If the grinding is done in two stages, suc as with ball and tube mills, the use of two sets of tank or bins is suggested; one set of at least four, and bette six or eight tanks to be placed after the preliminar mills (ball mills) and one set of four or more after th secondary mills (tube mills). The tanks in the firs set should be sufficiently large to take care of at leas four hours' run of the mill. The system should be pro vided with an automatic sampler so that the content of each tank can be sampled as ground. Where ampl rock storage had been provided to give fairly uniform rock, the four tanks could then be used in this manne One tank would be filling, the second tank would b under test and the third and fourth tanks would b used straight, or mixed if necessary to give the prope composition. When analysis proved a tank to be o incorrect composition it would be necessary to so pro portion the next tank that the two could be mixed s as to give a mixture of correct composition. Th second set of tanks would receive the fully groun material and these should also be provided with auto matic samplers. They serve as a further means o correcting the mix when necessary by blending th contents of two or more tanks as the pulverized materia is sent to the kiln. The mixing here is not as thoroug

s would occur when the two materials were ground ut still fairly good mixing would occur when the screw nveyors were used to carry the mix from the tanks nd considerable mixing would also be effected in the pper part of the kiln before the material began to rm into balls.

Suggested Method

At some plants, it would no doubt be found most nvenient to use such a series of tanks for mixing. hat is, to grind the materials separately to 10 to 20 esh before the mixing is done. In this case certain nks would be set aside for limestone and certain nks for clay and both materials would be sampled utomatically and mixed according to the analysis of ese samples. It is comparatively easy to secure an ccurate sample of 10- or 20-mesh material, while it is xtremely difficult to obtain anything which will prop-rly represent material crushed only to 1 in. So that is system of sampling, analyzing and mixing will do ith 10-mesh material but will not give satisfaction ith 1-in. material. The statement that the finer the aterial the easier it is to sample accurately will hold ood for all materials.

No doubt various modifications of this system would e devised to suit local conditions. For instance, at rtain plants it might be found best to mix partly by nalysis and then to do the correcting by adding to ie contents of the tanks as drawn a small amount f clay or limestone ground to 10 mesh. I am not ying to outline a plan to be followed by all plants, ut merely to indicate lines along which such a sys-m may be worked out. The cost of operating such system would be low and the initial investment small. believe the saving in other lines aside from quality ould pay for the installation and upkeep of the sys-m. Such saving would include fuel required to burn ver-limed mix, power to grind under-limed clinker, bor due to greater kiln outputs, greater life of kiln nings, etc.

Interdependence of Steps in Portland Cement Manufacture

In the earlier paragraphs of this paper, it has been own how the various steps in the process of cement anufacture bear one on the other. From this it ill be evident that if there are shortcomings in one ep these must be made up for in the next. If the mposition is irregular, the grinding of the raw ma-rials must be carried to the degree of fineness neces-ary to give sound cement from the high-lime mixture s well as from the low-lime. Every chemist knows at where the lime is high, much finer raw grinding s required than where it is low or even normal. In rder to make sure of sound cement, the chemist must herefore grind finer where occasional runs of high-me material are encountered than where the mixture s constant. The proper fineness of the raw materials s therefore influenced to some extent by their com-osition.

The proper burning of cement is largely one of feeding ie material and fuel to the kiln at a regular rate. If he composition of the mixture is constant, it is evident hat if the material is fed to the kiln at a regular rate nd the kiln is kept at a definite temperature and evolved at a constant speed, the resulting clinker will e uniformly burned. The trouble with the burning s, first, that the composition changes, requiring a higher temperature or a longer time in the kiln and, second, that the rate at which both raw material and coal are fed to the kiln is subject to violent and sudden fluctuations, or in other words, both coal and raw material "flood." Where trouble with the burning results, much of this can be eliminated by designing proper feeding arrangements for both raw material and fuel. The irregularities due to change of composition come gradually and can be kept up with, while the feeding of the raw material is usually sudden and the extra load of material occasioned thereby is hard to catch and properly burn. The arrangements for feeding slurry to the kiln, where this is done by positive means such as buckets and scoops, are excellent and something of the same sort of arrangement is desirable in the dry process.

Summary

The qualities most desirable in cement are soundness, strength and uniformity in the rate of setting and hardening. All are dependent to a marked degree on chemical composition, the fineness of the raw materials and the burning. These three steps are therefore the ones which must be under perfect control if quality cement is to be produced. The chemical composition should be regarded as the keystone of the arch. Unfortunately, it is the step least under control. While there are many plants where unsound or quick setting cement is a rarity, even here there might be an appreciable improvement in quality by a closer regulation of chemical composition. Most cement chemists are playing safe, as it were, rather than attempting to attain any ideals. Perfect control of the composition would enable them to make cements much higher in lime than they do at present, with the result that their clinker would be more easily ground and the resulting cement stronger and more uniform in setting and hardening qualities.

Iron and Steel Situation in Japan

Latest advices from Department of Commerce representatives in Japan indicate that the iron and steel industry has been adversely affected by the financial stringency and general depression which set in during April of this year. Prices have been unstable and weak, but as yet have shown only fractional declines. Stocks are increasing, while the volume of sales is narrowing. Despite the depression, however, Japan continues its purchases of iron and steel in considerable volume.

Imports of iron ore, pig iron, and iron and steel products into Japan during April amounted to 175,813 long tons, bringing the total of foreign iron and steel purchased by that country during the first 4 months of 1922 up to 686,047 tons.

In May of this year its purchases from the United States were 88,400 gross tons, or 5,000 tons more than in April.

Japan has always been a large buyer of United States finished steel products, and since November of last year has been our leading customer. In the year 1921 the Japanese market received 614,281 tons of rolled iron and steel, 566,722 tons or iron ore, 222,639 tons of pig iron, and 9,239 tons of scrap iron and steel. Of the rolled iron and steel tonnage, the United States supplied 59 per cent, and of the pig iron and scrap, 1,409 and 2,247 tons, respectively. In that year the United States furnished over 70 per cent of the 59,000 tons of rails imported by Japan.

The Native Paper Industry of Western China

By H. K. Richardson

PAPER has been manufactured in China since the beginning of the Christian era. Paper money is mentioned in the history of Szechuen as early as 960 A.D. Today this industry is carried on in much the same way as it has been for the past ten centuries.

Many different kinds of paper are made in the western provinces of Szechuen and Kweichow, of which four are of particular interest. These are:

1—Kou Pi Chih or bark paper, which is made from the paper mulberry, probably the original paper made in China.

2—Rice paper, so called, which is sliced from a pith.

3—Ts'ao Chih, or coarse paper, made from rice straw or reeds.

4—Chu Chih, or bamboo paper, made from young bamboo trees.

Each of these papers is made by a method more or less distinctive, so the manufacture of each will be given in detail.

Kou Pi Chih

The bark paper is made from the bark of the paper mulberry, *Broussonetia papyrifera,* a much-branched tree about 45 ft. tall with a smooth gray bark. Marco Polo in his "Book" states regarding the manufacture of this paper: "What they take is a certain white bast or skin which lies between the wood of the tree and the thick outer bark and they make something resembling sheets of paper, but black." Most of this paper is made today in Kweichow province, a region but little visited by white men, so there is little to add to the above description of the manufacture of this article. The process must have undergone some change, for this paper is rather gray, not black. It is the toughest paper obtainable in China. It is extensively used to wrap up rolls of silver dollars and to serve as the interlining between the fur and silk of the Chinese winter garments. In this latter case its tough texture prevents the sewed seams of the fur from wearing through the silk. This paper is considered by many to be the original "india paper," which actually was a Cantonese, not an Indian, product. The steamed bark of this tree finds use as string.

Rice Paper

This variety of paper, known as rice paper to foreigners, is made from the pith of *Tung Ts'ao* or *Tetrapanex papyrifera,* a shrub similar to our common ivy. The beautiful and strong white pith of this plant is rolled against a sharp knife in a manner similar to the way a veneer knife is applied to a log of wood. The result is a large piece of very white absorbent paper, much in demand for artificial flowers and artists' painting paper. One whole street in Chengtu is given over to the making of artificial flowers and butterflies, for which a large supply of this paper is needed. Many are the colors shown, for the paper takes dyes wonderfully well. The slicing of the paper is a trade in itself and is handed down from father to son. Much skill is required for this operation. It is usually carried on in the quiet of the night hours when no noise distracts, for the concentrated attention of the operator is needed to preclude serious accidents.

FIG. 1—PITS LINED WITH CONCRETE FOR DIGESTING THE BAMBOO CULMS

Ts'ao Chih

This variety of coarse paper is made more according to modern ideas from (*a*) rice straw, *Oryza sativa l.* or (*b*) *Mao Ts'ao,* a reed of the species *Imperata arundinacea koengii* or (*c*) a mixture of the above.

The apparatus used to make this paper is similar to that used for bamboo paper and will be described under that heading. The reduction process, although similar to that used for bamboo paper, is simpler and takes less time.

The straw is bundled and soaked in a pit of water for a month. It is then removed, washed thoroughly and stacked in layers in a dry pit, each layer being sprinkled with slaked lime containing 1 per cent soda. After removing the excess water and lime, the fiber is steamed and made up into a thin pulp with mucilage. The paper is made on a hand frame, after which it is pressed and dried, generally on the kiln drier described later.

This coarse, dark brown paper is familiar to the American boy as the inner tube of the Chinese firecracker. It is the wrapping paper for all foodstuffs, doing the work of our old butcher paper. Large quantities are punched full of holes to represent the Chinese cash—brass money with square holes—and burned at funeral ceremonies to provide the spirit with money to pay the ferryman across the River Styx. This paper is produced in large quantities, especially on the northern border of the Chengtu plain, where plenty of rice straw and water from the irrigation system are available.

Chu Chih or Bamboo Paper

This is the most interesting paper to the chemical engineer. The best paper produced in Szechuen is

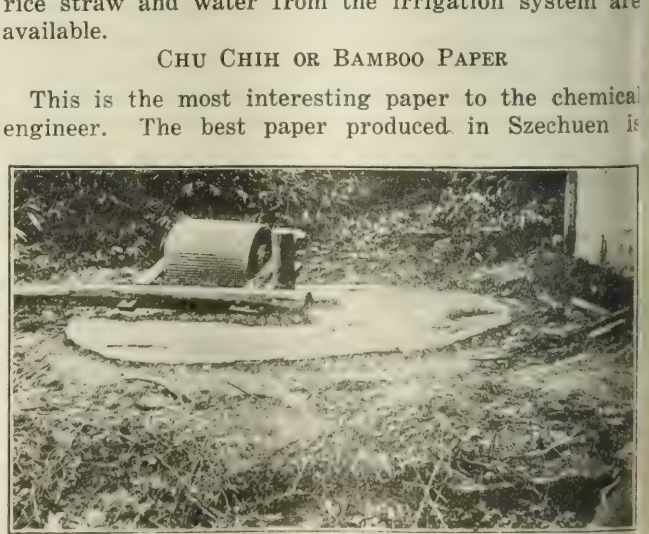

FIG. 2—STONE GRINDING FLOOR

de from bamboos. Since the process is said to be r ten centuries old, it will be described in detail.

More than thirty varieties of bamboo grow in west- China, of which only two are commonly used for per making. These are *Tzu Chu* or Spiny Bamboo, *mbusa arundinacea* and *Ch'ung Chu* or Grove Bam- , *Phyllostaclys heteroclada*. The second is used by st paper makers. This variety grows to a height of to 18 ft. and is 1½ to 2 in. in diameter. It grows its full height in about 2 months, naked of leaves. hen the full height is attained leaves spring out at h joint, which roughly represent each day's growth. st Chinese paper makers prefer to use the young lms before this leafing-out occurs, for they say the fing-out process hardens the nodes and makes them ficult to reduce by the usual retting process.

Manufacture of Paper From Young Bamboo

The process used to turn this bamboo into paper ries a little in the different parts of the province. ie process as it was observed in the district along the engtu-Wanhsien post road will be outlined first; and e differences as given[1a] by other observers for other portant centers will then be mentioned.

The bamboo is first cut into 8-ft. lengths and then lit lengthwise into eight parts. The split cane is d in pits with alternate layers of lime, about 10,000 tties of bamboo with 1,000 catties of lime making a charge. The matted bamboo is weighted down th stones and covered with water, in which condition is permitted to stand for 2 months. The bamboo then removed, washed and soaked for 2 months in an water to leach out the lime. The water is drawn and the mass permitted to ret in this moist condi- n for 2 months, after which it is hammered to a lp in a mortar or stone mill and finally is rubbed a fine pulp in a stone trough by stamping under ot. This pulp is mixed with cold water and mucilage stone vats, after which it is dipped out on hand ames which are stacked in a press and pressed semi- y. The sheets are dipped singly into rice water and e then dried on the side of a hot kiln.

Hosie and Wilson describing the same process state at the first reduction of the fiber is done in the vats th wooden rakes. They also state that 1 to 3 per nt of soda is added to the slaked lime in the retting ocess. It is known that caustic soda is sent to the ung Chow and Mien Chu districts for paper making importing firms. This use may account for the ct that the paper from these districts is whiter and tter than that from the other districts. Probably a uch larger amount of caustic would be used if the 00 a ton freight charge and the extra importing mmissions did not make the price almost prohibitive.

Apparatus Used

Concrete Vats.—A deep hole 12x6x5 ft. deep is g in the ground and lined with Chinese cement— ne, mud and crushed brick. In these pits, one of hich is shown in Fig. 1, all the treatment with lime release the fiber is carried out.

Pulp Reducers.—The well-retted bamboo is first re- ced in either a giant mortar and pestle by man- wer or more usually by cow-power on a stone grinding or. Such a floor is seen in Fig. 2. A grooved lime- one roller is hauled around the post counter-clockwise, eaking up the bamboo on the floor. To clear the floor, ie direction of rotation is reversed. The pulp is moist in this operation. The pulp thus prepared is broken up finer by being trodden under the feet of men in an inclined ribbed stone trough, such as is shown in sketch of Fig. 3.

Mixing Vats.—The well-trodden pulp is mixed up with mucilage from the Hibiscus plant in stone tanks 80x30x30 in. deep. These are made from red sandstone slabs 2 in. thick, made watertight by use of china-wood oil putty—i.e., whiting plus the oil.

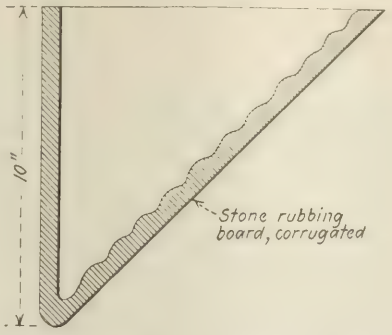

FIG. 3—CROSS-SECTION OF STONE RUBBING TROUGH

Paper-Making Frames.—The paper-making frames are a stout framework of bamboo slats with end handles. A split bamboo netting woven in a fine mesh lays over the slats. The longest papers are about 60 in. long and 23 in. wide, so these nettings are a clever piece of bamboo workmanship. An edge clamp extending the length of the frame keeps the netting from floating. In use the frame with the netting is dipped down endwise and sidewise into the well-stirred pulp and gently lifted in a line parallel to the surface, so that a uniform layer is produced. The clamp is lifted, the sheet permitted to drain and the netting turned upside down on the pile of sheets already made, thus causing the new sheet to stick to the pile so that the netting comes loose. The sheets are piled in the bed of the press.

Presses.—When a pile of paper sheets about a foot high is collected in the press bed a board is placed on top, blocks are inserted and the power applied. This is done by means of a capstan and bars. Fig. 4 shows a complete outfit of tank, frame and press. The press is to be seen through the slats of the frame from which the netting is removed. A spring came out of the hill in the rear of the tank so that water was available. Practically all the paper work observed was done in open sheds like the one shown, a thatched roof being the only protection from sun and rain. The mild climate permits this economy.

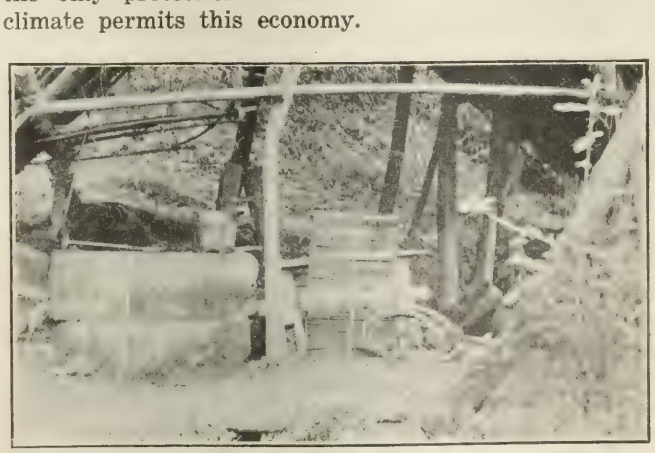

FIG. 4—STONE TROUGH, WOODEN FRAME AND CAPSTAN OF PRESS (SEEN THROUGH SLATS OF FRAME)

Name of Paper		Size Sheet Inches		Cost Per Sheet		
Chinese	English Translation	Length	Width	Chinese Cash	U. S. Cents	Uses
Hsu Peh Chien	White	60.5	12	25	1.0	Writing and printing books.

Drying Kilns.—Fig. 5 is a cross-section of the kilns, which are nothing more than plastered flues. Some are 24 ft. long. The pressed, moist paper is spread out on the plastered sides of the kiln and permitted to dry. When a workman has plastered up the whole side with sheets, the first sheet is about dry and peels off, so he can start right over the side again, removing dry paper and putting on wet sheets. These simple kilns are wonderfully efficient and cheap. Straw is the usual fuel.

Sizes of Paper Made.—In an investigation made to see if a modern paper mill was an economic proposition in Szechuen, samples of the most used papers were collected. Since these give a good idea of the skill reached by the native paper maker, the data are reproduced in the accompanying table. The original sheets were sent to a well-known industrial laboratory which was co-operating in the survey. It is interesting to note some of the unusual uses to which the paper is put, such as window panes—a very large use, as there is little glass is used in Szechuen—and funeral ceremonies.

Economics of the Industry

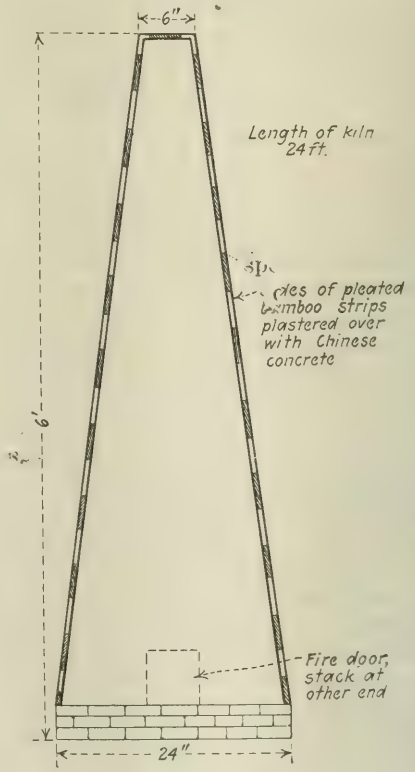
The centers of production of paper in the province are Mien Chu, Chung Chow, Chia Chiang, Lu Chow and the Ta Chu districts. Each is famous for a particular kind of paper. Mien Chu makes the best fine-texture bamboo paper, while most of the straw paper comes from Lu Chow. All the industry is in the hands of small proprietors. It is somewhat seasonal, as the old pulp is just about used up when the new bamboo is ready for cutting.

Four men were required to make a stack of bamboo paper 48x13x30 in. in the Ta Chu district in order to earn 640 cash or 21 cents for the four per day. One man prepared the pulp, one man handled the frame and two operated the drying kiln. All the work was piece work so any extra inches of paper made was paid for at proportional rates. All material and apparatus were furnished by the owners of the plant.

Some of the paper is dyed through, some only on one side, both native and aniline dyes being used. Glossy paper for visiting cards and note paper is glazed by rubbing white insect wax on to the surface with a smooth hard stone.

Modernization of the Industry

We know of only one attempt to erect a modern type of paper mill in Szechuen. This mill was to supply drawing paper for the modern education movement that started about 15 years ago. When the writer first saw



6"
Length of kiln 24 ft.

24"

FIG. 5—CROSS-SECTION OF PAPER DRYING KILN

the mill it had been closed down for over 2 years. An investigation was made to see if a real plant could be grafted upon the ruins. The reasons for the failure of the mill are such as frequently beset Oriental enterprises and are as follows:

1. Plant was wrongly located, since the raw material for the kind of paper wanted had to be imported from Japan. This meant that for every pound of paper produced 2 to 3 lb. of raw material had to pay a freight rate of $200 per ton. Thus Japanese paper, in spite of cheaper Szechuenese labor, could sell for less than the local product.

2. The local market for the paper produced was not of sufficient size to run the plant at a reasonable percentage of capacity, so the paper produced had a very high overhead charge. There was no export market, as will be seen from reason No. 1.

3. Officials who had supplied part of the funds to finance the undertaking demanded dividends from the day of investment. It takes 18 to 24 months to get machinery from abroad to the interior of China and have it set up and in working order, so this requirement was a severe drain on the liquid funds of the enterprise.

The estimate of the value of the existing plant as the basis of a new enterprise was not sufficiently attractive

o interest the new investors, so the plant was permitted o settle back into the discard.

Since the native plants have seen the advantage of austic soda a good demand has sprung up for this naterial. British merchants supply most of the de- nand. There is a good chance for an electrolytic austic-bleach plant in the paper regions if the central overnment could be influenced to forego the present rohibitory tax on the necessary salt. Hydro-electric ower could be developed in most of the paper sections ery cheaply.

The present craze for newspaper publishing in China as given rise to a demand for paper of better quality han the best bamboo paper. At present all this paper omes from abroad, making a 10,000-mile trip to the nterior and paying the large freight rate spoken of efore. The risk of spoilage that accompanies so many ehandlings and water transport in the rapids of the angstze River adds considerable to the expense. Con- iderable research will be needed to get a paper of ufficient strength for printing presses of modern type, ut experience in India has demonstrated that bamboo aper of high quality can be made with a competent echnical organization. Bamboo grows so quickly that n abundant supply of raw material is always at hand, o that a fairly large modern paper mill could be run n this part of the world and be assured an abundant upply of raw material and a ready market for its roduct.

Legal Notes

By Wellington Gustin

Refining Company Responsible for Escaping Oil Causing Damage to Overflowed Lands

In an action brought against the Midwest Refining o. the Sussex Land & Live Stock Co. charged that it as committing a nuisance in permitting oil from wells n the Salt Creek oil field operated by it to find its way nto Salt Creek, and upon occasion of floods in that reek to overflow with the water upon plaintiff's pasture nds, damaging the pastures. Plaintiff sought to en- in the refining company from permitting the escape f the oil in the manner indicated and asked damages of pproximately $222,140.

The Refining company denied the escape of any sub- antial quantity of oil upon plaintiff's land, and denied here was any damage in consequence of the escape of ny such oil; that the damage, if any, was caused by he natural escape of oil not within its control. It rther contended that the damage, if any, was largely ntributed to by other practices, and that the oil field, far as the defendant was concerned, was operated rough modern, scientific and best-known methods hich would in law relieve the defendant of any damage n account of the escape of oil. And further it argued at if damage were caused through the operation of e oil field by itself in the manner indicated, in any ent an injunction should not issue, on account of the blic welfare, including the vast amount of money volved, the great number of employees engaged in the terprise and the life and prosperity of entire com- unities being largely dependent upon the continued eration of the field.

The District Court for Wyoming, after hearing testimony covering 3 weeks, entered a decree providing that if within 60 days the Refining company pay plaintiff damages assessed in the sum of $2,880 with costs of the suit, and further pay the sum of $720, the annual rental of the lands, yearly the injunction would not issue, but otherwise the injunction to issue restrain- ing the Refining company from the commission of the trespass upon the lands.

Rental Value of the Land Is Measure of Damages

Further the court says that in such cases where damages result from oil escaping into a stream and carried over lands upon the overflow of the stream, the measure of damages may be based upon the usable value of the lands as measured by loss of profits, or upon the rental value of the land. Here the proper measure of damages was the rental value of the land.

The court further says that the damage to a going business by another either on account of negligence or the commission of a continuing trespass may be the loss of prospective profits, providing they are proved with reasonable certainty so as to take them out of the realm of speculation, uncertainty and remoteness. In this case there was insufficient evidence to show plain- tiff's profits before the damage as compared with his profits after the damage, and therefore the court held this would not justify an award for loss of prospective profits. Accordingly the rental value of the land was all plaintiff was able to recover from the Refining company.

Damages for Refusal to Accept Goods

The damages for refusal to accept goods are the difference between the market price and the contract price at the time and place of delivery, says the Ap- pellate Term of the New York Supreme Court in an action brought by Robert W. Bonynge against the Carex Company, Incorporated, 188 N. Y. S. 750.

It appears that the Carex Company bought of plain- tiff 50 barrels of acid in March, which product was duly tendered in June to the company, which refused to accept delivery, but requested the sellers to hold said goods for its account, agreeing to pay the storage and insurance charged. But between July 29 and Nov. 1 of the same year, the sellers sold the acid at the best prices obtainable, the result being a difference of some $1,093, for which they brought this suit, together with certain storage charges.

Price Difference on Delivery Date Basis for Fixing Damage

It was not denied that the seller was entitled to a judgment for failure of buyer to receive and pay for the acid, but the buyer contended the measure of damages should be the difference in the contract price and the market price on June 1, when the acid was tendered for delivery. The seller contended that the buyer's request that the goods be held by the seller for its account amounted to a "waiver" of its right to object to complainant's failure to resell on that day. However, it was not shown that the seller agreed to such extension of time, nor was there set out any definite time for the extension to agree to. Having not shown any agree- ment for an extension of time to the buyer to receive and accept the acid, the court held that there could be no recovery for the difference betwen the contract price and proceeds of resale at a later date because of the buyer's request for extension of time.

The Technology of the Carbon-Electrode Industry—IV Grinding, Mixing, Molding and Extrusion

These Important Steps in Production as Carried Out in Modern Electrode Plants Receive Critical Attention, With Special Reference to Effects Produced by Various Types of Equipment — Other Factors Affecting the Quality of the Finished Carbons—Inspection and Grading*

BY CHARLES L. MANTELL
Division of Industrial Chemical Engineering, Pratt Institute, Brooklyn

IN PRIOR articles of this series the discussion has been carried through the selection and calcination of the carbonaceous materials used in the manufacture of carbon electrodes. The next step in the production process is that of grinding. The calcined materials (coal, coke and petroleum coke) are delivered from the calciners in sizes varying from fines to the largest pieces that will pass through a 3-in. screen.

To obtain the greatest density and highest tensile strength in the finished electrode, it is necessary for the pulverized material to be graded properly—that is, to be composed of a mixture of large and smaller particles in a definite proportion rather than entirely of uniformly sized particles. The theory is that the smaller particles fill in the interstices between the larger ones and thus reduce the porosity of the mass and also increase its density. It can easily be shown that the porosity is the same in a mass of round particles of the same size, regardless of their dimensions.

Reasons for Pulverizing

Pulverizing is done with either of two ends in view: (1) To obtain the desired or as near as possible the desired grading by grinding all of the material in a mill which has been arranged to give the specific grading, or (2) To obtain the desired grading by screening the differently sized components of the pulverized material into various divisions and later building up a second mixture of the proportions desired.

Both of these methods are used, the latter principally in Europe and not at all in the United States. The second method tends to become complicated, as there is likely to be, at some time or other, an excess of some division of the pulverized material after screening. The second method involves a number of tanks for the screened material, a number of weighings and proportionings of the separate divisions of the screened material and a remixing to cause the large and small particles to be uniformly distributed throughout the mass.

Inasmuch as most electrodes are made of at least two carbonaceous materials, it is not necessary to go to the trouble of separating the various sizes of pulverized materials. Grading of the particles may be accomplished by pulverizing one material finer than the other, and mixing them in the proportions desired.

The unit most largely used in American practice for pulverizing the calcined material is the roller pulverizer with air separation. This machine requires a feed of material of approximately 1-in. size for efficiency operation at maximum capacity. It is usual therefore, to pass the calcined material through a roll crusher in order to break it down from 3- to 1-in pieces, preparatory to sending it through the pulverizing mill. These crushers are corrugated rolls, equipped with reciprocating plate feeders.

Butts, the unconsumed portions of used electrodes constitute a large portion of the raw material of electrode plants supplying certain industries, such for instance as the reduction of aluminum. Butts are generally hard, tough and somewhat brittle. Their pulverization for re-use presents a more difficult problem than grinding petroleum coke. Former practice was to crush them first in a rotary crusher and then feed them to a ring pulverizer or a roller mill. Under present practice greater capacity per machine is obtained by first cracking and crushing the butts in a jaw crusher, then after picking out metals and other contamination they are run into a rotary crusher and finally are fed to a roller mill.

Pitch Grinding and Storing

Practice as to grinding pitch differs in the various plants according to the mixing requirements. Some plants obtain satisfactory results by merely coarse grinding the pitch in a rotary or a gyratory mill after the material (as it comes from the still) has been broken up in a corrugated roll crusher. This method gives a ground product varying in size from fines to pieces passing through a 2-in. ring.

The second method is to fine-grind the crushed pitch in a mill of the swing hammer type. This yields a product all of which is smaller than $\frac{1}{8}$ in.

The storage of great quantities of finely ground pitch is a difficult problem. If large masses are left undisturbed for several weeks, it will be found that the lower portions of the pile have regilated, or run together much like ice when it freezes. The pile can be broken up only by pickaxes, air drills or blasting. For this reason it is common practice in electrode plants using finely ground pitch to grind only a single day's supply in advance.

Pitch dust, according to tests in the explosion gallery of the Bureau of Mines, is very explosive. This is due to its high percentage of volatile matter. The grinding of calcined petroleum coke and calcined coal on the other hand, is attended with very little hazard since these materials have had practically all of the volatile matter driven off.

Pulverized materials are usually stored in large closed steel tanks, elevated from the floor and having outlets at the bottom. Material of this fineness flows

*Part I of this series of articles reviewed the history of the electrode industry and appeared in *Chem. & Met. Eng.*, vol. 27, No. 3, p. 109; Part II, discussing the raw materials, was published in vol. 27, No. 4, p. 161; Part III was concerned with the calcination process and is to be found in vol. 27, No. 5, p. 205.

very readily and accordingly leaks out through every small opening much as if it were a liquid. Two devices which are successfully used to control the flow of pulverized material of this sort are the "blast gates" or "coal cocks" made by the manufacturers of pulverized fuel equipment.

Soft pitch is melted prior to use or else a supply is kept in a melted condition. When tar is employed as a binder, it is usually thinned by heating so that it will flow more easily and can be more readily measured. Summer oil, another constituent of the mix, is usually stored in large tanks, from which it is piped to the mixer room.

Mixing Practice

Proportioning of materials is usually done by weight in the case of solid substances, and by volume in the case of liquids. The solid materials are drawn from their various tanks and weighed into the mix box in the proportions desired. Experience with table proportioning machines has been generally unsuccessful because the dust is so lively that it would flow over the tables of the machine and would not assume a position of rest which is necessary for the operation of the machine. The dial type scale has been successfully used for weighing dusts. In operating this, a workman permits dust from one tank to run into the mix box until the required weight is obtained, and then closes the valve on one pipe and opens it for the supply of the next constituent, thus making the operation continuous until the mix is obtained. No matter how clever the workman was, some poorly proportioned mixes would slip through.

An improvement in proportioning mixes has come with the installation of automatic weighing machines. Separate scales are used for each material, each scale dropping its charge into a common hopper which empties into a mix box. They operate on the balanced beam principle, discharge through toggle mechanisms when they have weighed their charge, and after discharging, return to position for another weighing. They can be set for any number of successive weighings without interruption.

The weighed dust, along with the binder if it be hard pitch, is dumped from the mix box into the mixing machine. If the binder has not yet been added, it is poured or run in some time during the mixing. Mixes with pitch as a binder are not stored for any great length of time after being proportioned, as segregation may take place and make it difficult to produce an even and uniform mix.

The mixing machines are heated by steam jackets and have some sort of provision for loading and dumping of the charge. One type, which is perhaps the most used, consists essentially of a steam-heated drum mounted on its side. Mixing is accomplished by rotating a central shaft with arms attached to it. The forward tilt of the arms, which during rotation carry the mix forward, finally discharges it through the door at the end of the drum.

The object desired in mixing carbon is to use as little binder as possible and still have the material extrude from the die and not crush or fall to pieces. The condition which is desired in making a carbon mix is to cover each particle of dust with as thin a film of binder as possible, so that when the various particles come in contact they will be well bonded together. Theoretically it is possible to calculate the minimum amount of pitch necessary to accomplish this purpose and several attempts in this direction have been made by the National Carbon Co. The practical difficulties met with in carrying out experiments of this type are practically insurmountable, due to the inability to obtain the size of all the particles. Fortunately, however, an experienced mixing and pressroom foreman who has had the proper training, can gage the amount of binder in the mix he is using so closely that if ½ lb. of binder per 100 lb. of mix is removed from the mix, it will cause the product to come from the extrusion press badly cracked.

Pan rolls are used both in this country and abroad for the purpose of obtaining a more uniform and denser mix than that given by the mixer alone. As far as the writer has been able to ascertain, they are not used for rolling a mix with a hard pitch binder.

Comparison of Molding and Extruding

But to return to the flow of material itself, it is delivered from the mixers to the presses for the shaping of the electrodes. This can be done in two different ways. One is by placing the mixed material in a mold and subjecting it to great pressure. The other is to place the carbon mixture in a cylinder, and by means of hydraulic pressure force the mixture through a die or mouthpiece of the requisite shape. Electrodes made by the first method are termed "molded," and those by the second extruded or "forced." Both the methods produce products that are homogeneous and of low porosity. The molding process usually results in a higher density electrode.

Extruded electrodes are usually used for electrolytic work. The reason for this is that it is easier to make the sizes of electrolytic carbons by extrusion, as only one or a few dies are needed, while many molds would be required to produce the same result by the molding process.

Due to the rapidity of the process, small electrodes are usually made by extrusion. Large electrodes can be made by both methods, those made by molding being preferred because of their higher density. Extrusion presses are now made so that electrodes as large as 36 in. in diameter can be produced by this process.

In the case of large electrothermic electrodes, the high density and low resistivity of the electrode are not as important as when smaller currents are used.

The equipment usually used for molding consists of the dies of the shape of the finished molded article and upright hydraulic presses to compress the materials in the mold. The molds are made of steel, or in some cases of heavy cast-iron construction, for they must stand great pressure.

The mixed material is placed in the mold as compactly as possible with enough extra material as has been determined by practice to compensate for the compression and still have the finished article fill the mold. The mass is pressed to shape between the top and the plunger of the hydraulic press. It is stated that pressures as high as 25,000 lb. to the square inch are sometimes used. Mixes for molding are generally made with pitch binders. The articles are removed from the mold as soon as they are cold enough to hold their shape, excess material is removed and the mold cleaned and lubricated for the next pressing.

Extrusion is a much more rapid process than molding, requires less labor per ton of material produced when the same size is produced in quantity. Since

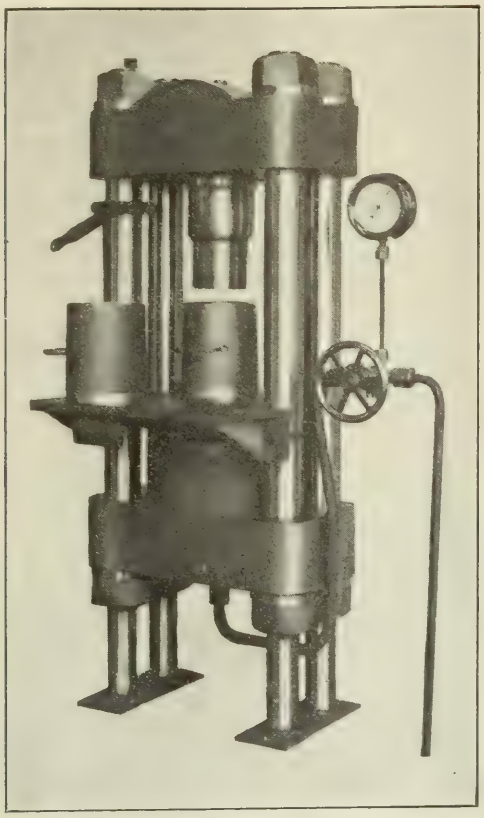

FIG. 12—A 250-TON VERTICAL SLUG PRESS FOR SLUGS 7-IN. IN DIAMETER

most electrodes are made by that process, extrusion will therefore be considered in somewhat greater detail in the paragraphs which follow.

In making electrodes by the extrusion method the hot mix is first "slugged" in the slug presses. These are vertical hydraulic presses, examples of which are shown in Figs. 12 and 13. The hot mix is placed in the mold or "pot," as shown in the illustration, and the material is compressed between the head and plunger of the press. This operation serves only to shape the mix and give it a form in which it can be readily handled. The slug is removed from the pot and is sent forward to be fed to the extrusion press.

Slug presses are normally operated at low pressures —that is, between 800 and 2,000 lb. per sq. in. Often it is necessary to employ some sort of lever arrangement, as is shown in the second illustration, to knock the slug out of the mold. As shown in Fig. 13, this is directly over a hole in working table of the press, through which the slug drops out to the floor or platform beneath. Automatic slug presses, capable of much greater capacity and entailing a much less physical effort on the part of the workmen in slugging the material, are replacing the type of press here illustrated. These are built with revolving tables, the pots being locked in place on the table. Three pots are used, one being filled with the material, another being compressed and a third discharged.

Slugs are made cylindrical in shape, the height being as great as permissible and still allow the slug to be easily handled. Slugging serves to remove occluded air and gas from the carbonaceous mass. The slugs are kept hot and are fed into the "mud" chamber of the extrusion press. This is the steam-jacketed cylindrical section of the extrusion press that serves as a loading chamber. Illustrations of extrusion presses are shown in Fig. 14. This type of press is used for electrodes from 2 to approximately 8 in. in diameter.

Extrusion Pressing

Extrusion or "plug" presses, as they are often called, are operated at hydraulic pressures as low as 1,200 lb. per sq.in., to as high as 7,000 lb., the variation being caused by different plasticities of the carbon mix. Operation is arranged to obtain mixes which extrude at approximately the same pressure. Opinions as to extrusion pressures favoring best results differ somewhat in different plants, but the usual range is between 2,000 and 4,000 lb.

In operation the extruding ram of the press chamber

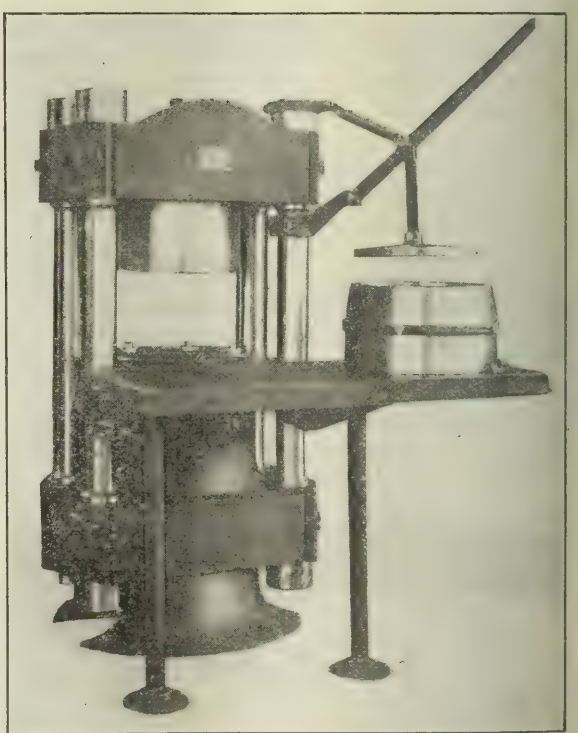

FIG. 13—A 350-TON VERTICAL SLUG PRESS

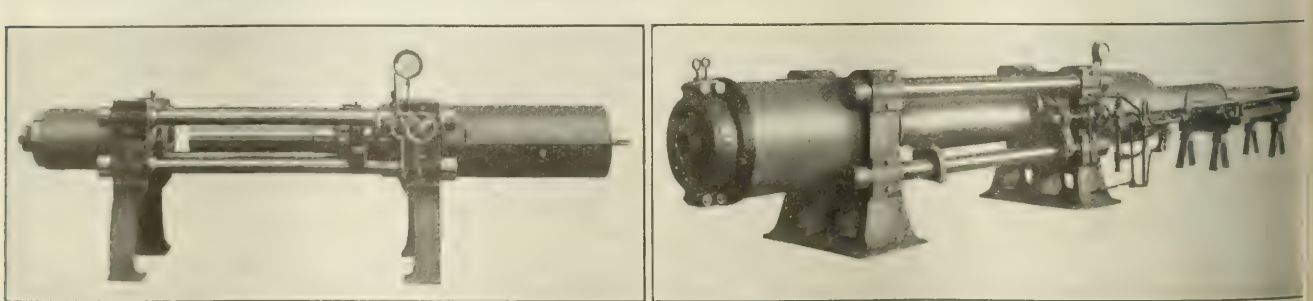

FIG. 14—A 300-TON (AT LEFT) AND A 350-TON (AT RIGHT) HORIZONTAL EXTRUSION PRESS

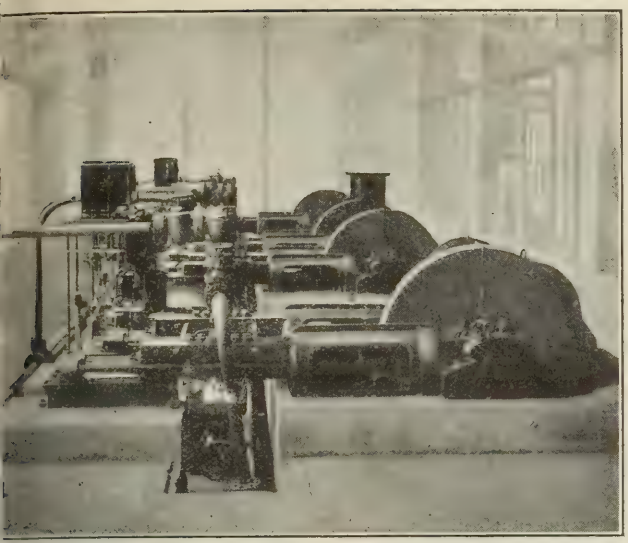

FIG. 15—INSTALLATION OF FOUR 6,000-LB. PRESSURE HYDRAULIC PUMPS FOR ELECTRODE EXTRUSION

s filled with low-pressure water and the ram moves up) and against the carbon slugs in the mud chamber. (igh-pressure water is then turned into the chamber being bypassed when not used) and the ram pushes ne carbon mass out through the mouthpiece, at the ame time pulling the backing ram forward and thus mptying its chamber. When the stroke is finished,)w-pressure water is run into the backing chamber, ushing the backing ram out of the chamber. The acking ram pulls the extruding ram back to position, mptying the extruding ram chamber. When the ex-uding ram is back in position, another load of slugs usually six), are fed in and the cycle repeated.

The size and shape of the extruded electrode will aturally depend upon the shape of the die or mouth-iece. Tubes can be extruded by the use of a spider etting, placed in the throat of the mouthpiece. The ngth of the electrode is limited only by the capacity the loading chamber of the press in terms of the olume of the electrode shape.

The carbons, after being pressed and shaped, are rmed "green" to distinguish them from the finished id baked electrode.

Fig. 15 shows an electrode plant installation of four orizontal 60-gal. 6,000-lb. pressure hydraulic pumps ipplying power for extrusion.

A Typical Installation

Fig. 16 shows a typical installation for extrusion. n overhead monorail crane carries mixes in a mix ox (*B*) to hoppers (*H*) on the third floor, located, one a machine, directly over the mixing machines (*M*) the second floor. The dust and binder have pre-ously been proportioned in an adjoining dust storage ilding. The materials are mixed, and discharged om the machines into a dump car (*C*) traveling on acks in front of the mixers. The dump car discharges to a hopper (*S*) feeding the pot (*P*) of the slug press *P*). The slug press discharges onto a platform (*L*), om which the slugs are conveyed on a roller carrier the extrusion press loading table (*LL*). The slugs e loaded into the extrusion press (*E*), extruded rough the mouthpiece of the press hot, cut to length a cutting knife mounted on a table next to the die, d dropped into the cooling tank (*C*), which consists of a wood slat conveyor running under water. The green electrodes are discharged from the cooling tank onto an inspection table, inspected, loaded onto weighed truck, and transported to the baking furnaces.

Conditions Affecting Mixing

The mixer and press rooms are the heart of the electrode plant. The quality of the finished carbon is largely dependent upon the quality of the green carbon extruded. A good green carbon will usually produce a good baked one if baking conditions are right. A poor green carbon will never produce a good product no matter how well the baking operations are conducted.

Mixing practice differs even in plants making the same kind of electrodes for the same purpose. Practically all mixing is accomplished by cut-and-try methods and the test as to whether a mix is finished or not is to take up a handful of material and "feel" it. If it "feels" as past experience has shown the mixer man a good mix should, it is finished. It is practically impossible to proportion a mix on paper and have it actually work out in that desired manner.

Most of the difficulties of mixing are due to lack of uniformity of the binder. There is as yet no satisfactory method of determining the binding power of a binding material except actually trying it out. The binding power of pitches varies more or less with their melting points, but differences in the method of manufacture make it possible to have two pitches of nearly the same melting point with widely different binding properties. The thing of greatest importance about pitch and mixing methods is that the pitch be uniform at all times. A good carbon can be made of high-melting pitch; likewise a good carbon can be made of low-melting pitch, but if there occurs, in the course of the day's work, several batches of high- and several batches of low-melting pitch, naturally the carbons themselves will not be uniform in their characteristics unless the mixing and forcing conditions are changed accordingly.

While the melting point has the predominating influence on a mix, the fact that the insoluble residue, which is carbon also, has its effect should not be overlooked. Its effect is not as pronounced as the melting point, for it does not vary so greatly. Obviously a pitch with a

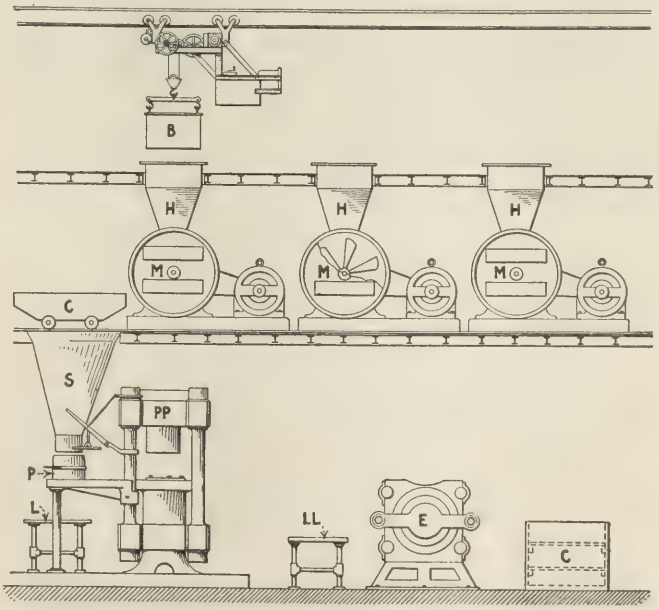

FIG. 16—A TYPICAL INSTALLATION FOR EXTRUSION

high residue will have to be used in greater quantities with a given amount of dust than would be the case with a pitch of low residue, for this residue is finely divided carbon.

Good carbons can be made whether the pitch is finely ground, crushed or melted, but the actual mixing and forcing conditions will vary with each process. Naturally if the pitch is already melted it need not stay in the mixer so long to give a good mix, but there will be some difficulty in adding the pitch so as to keep it from coagulating or agglomerating when it touches the dust. To prevent this it would be necessary to have the dust at the same or nearly the same temperature as the added pitch. Melted pitch can be added to a cold flour and a good mix obtained, although the chances are it would take a higher mixer temperature and a longer mixing time.

A good mix can be obtained by finely grinding the pitch and adding it to the mixer either with the flour or after the flour has been put into the mixer and become heated. A good mix can be obtained by using a pitch crushed in a gyratory crusher, as is the practice at some of the Niagara Falls plants, but here again the same mixing conditions must not be used as with pitch which is melted or more finely ground.

Factors in Green Electrode Production

Table IV shows the most important factors in green carbon production by the extrusion method. Volatile matter (1) has been discussed under calcination, moisture (2) just previously, fineness (3) and grading (4) under grinding, and chemical analysis (5) under raw materials. The effect of uniformity of melting point (6) has just been explained. The term long range of viscosity (7) refers to the amount of change per temperature deg. C. of the viscosity of a pitch. Viscosity is more or less a measure of binding power; for a pitch to have a small change of viscosity per degree means that its binding powers are practically the same over a wide temperature range. Such a pitch would be more desirable than a narrow range viscosity—one whose binding powers change rapidly with temperature. A pitch with a high coking value (8) is preferred, as less of it would distill off in baking and be lost. The grinding (9) of pitch, minimum amount of binder (10) and the grading of dusts (11) have already been touched on. Since pitch has a much lower density than carbonaceous materials, any excess over that needed in the mix tends to lower the density of the green carbon. A green carbon of lower density has its effect in lowering the density of the finished electrodes. The factors (12-14) affecting mixing have already been discussed.

It is necessary to carry out the slug pressing (15) more rapidly with a mix containing a high-melting pitch than with a low one, since the higher melting mix does not remain soft and workable as long as the low. The apparent density (i.e., weight divided by apparent volume) of the green electrode will be largely affected by the pressure (16) employed in slugging. Naturally, within limits, the higher the pressure the greater will be the density. The apparent density of the extruded carbon is usually only two or three points above that of the slug. Uniformity of temperatures (17) is important, as slugs made at different temperatures will have different plasticities and different extrusion pressure. In the plug press one slug is likely to push through another. Lack of unformity of slug temperatures is held to be the cause of "core carbons," a defective product which must be scrapped.

INSPECTION

24. Scrap

The pressure of extrusion (18) depends upon the plasticity of the material. The addition of summer oil to the mix reduces the extrusion pressure. Excess pitch results in more plastic mixes and lower extrusion pressures. Cold mixes require higher pressures, as their plasticity is less because of the freezing of the pitch. The temperatures of the mud chamber (19) and dies affect both the extrusion pressure and the surface appearance of the extruded carbon. With a colder mud chamber and die the friction between the mix and the walls of the chamber and die becomes greater and additional pressure must be used to overcome this. Summer oil is usually used as a lubricant for the inside of the mud chamber and for the head of the extruding ram. With too hot a mud chamber and die, the carbonaceous mass will be heated, locally probably, and may rise to a high enough temperature to cause some of the binder to distill, evolving gases which break through the outside surface of the green electrode. The temperature of the extruded carbon (21) is affected by the temperature of the original mix, the rate of its cooling and the temperature of the mud chamber and die. It is not desired to have an extruded carbon so hot and plastic that handling destroys its shape. It must be cold enough to retain its form and still hot enough to be extruded.

Summer oil in the mix, lessening the binding power of the binder, permits greater ease in cutting (22) than the same mix without summer oil. The closer the mass comes to falling apart at the die the easier it is to cut up the extruded stream into lengths. Excess pitch makes the mass tougher and more difficult to cut.

The temperature of the cooling water in the tank (23) should not be too low, otherwise there is the danger of having the electrodes split. This may be due

o the contraction of the outside shell (from the sudden reezing of the pitch caused by the abrupt change of emperature) around an internal mass still quite hot. The outside shell may not be strong enough to stand he resistance to compression from the inside and the uter shell splits at the weakest point.

Inspection and Grading

Inspection at the tables at the end of the cooling tanks eparates the passable electrodes from those which go o the scrap pile. Good electrodes must be of proper lensity, have smooth outside surfaces, be free from ross checks or splits, contain no cores, unmelted pitch r foreign material, be cut to proper lengths, be cut quare and be well shaped.

The following is a classification of reasons for rejection due to physical defects: (1) Splits. (2) Core carons. (3) End splits. (4) Distorted in shape. (5) Pitch (in excess). (6) Die rings. (7) Enlarged ends. (8) Oval ends. (9) Blistered skins. (10) Cross checks.

Representative samples of these defects in small ound electrodes may be observed from the photographs reproduced in Figs. 17 to 23. The nature of these defects and their causes are discussed in the following paragraphs:

Splits. Splitting of electrodes occurs at the die, at the cutting table and in the cooling tanks. The size of the fissures may vary from a length just perceptible to the eye to the full length of the carbon. The width of the fissure may vary from a very slight crack (as shown in carbons 2 and 6 of Fig. 17 between the chalk marks on the carbon) to easily noticeable defects (as carbons 3 and 8). All, however, are equally undesirable.

Cores. In extreme cases of "coring," the inner cylinder may be separated from the outer shell. If core carbons such as are shown in the "B" pile in Fig. 18 are baked, the inner cylinder may be easily pulled out of the outer shell. The lines of division between the shell and cylinder may be arcs or complete circles. Sometimes an indication of coring may be found at only one end of a carbon.

End Splits. Fig. 18 "A" needs little description. The defect varies in size from a hair line to a quarter of an inch in extreme cases.

Pitch Carbons. The six carbons on the left-hand side of Fig. 19, if examined closely, can be seen to contain pieces of unmelted pitch.

Distorted Shapes. The three carbons at the right of Fig. 19 were rejected because of their distorted shapes. Even if satisfactory for some use, it would be difficult to load such distorted carbons into the baking furnaces.

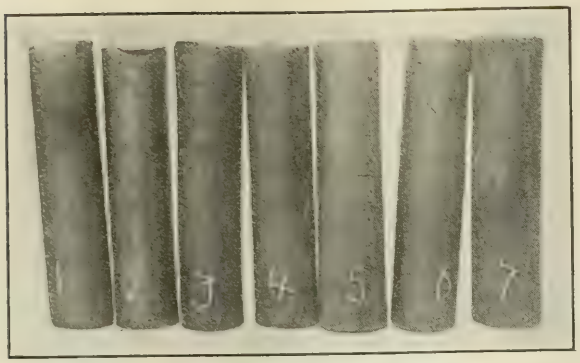

FIG. 23—CROSS CHECKS IN CARBONS

Die Rings. Die ring carbons usually occur at the first carbon of a push. The carbons are scrapped because of possible weakness at the rings and because of difficulties in loading and unloading in the baking furnaces.

Die ring carbons may be roughly divided into two classes. (1) Those produced during a push when for some reason the press was stopped and started. It will be noticed in Fig. 20 that carbons 3, 4 and 5 show a slightly smaller diameter of carbon above the ring than below it. These carbons were produced during a push. The lower portion was the part of the carbon protruding from the press. The protruding portion had expanded slightly. (2) Those produced by an operation analogous to a weld—this is to say, a union made between material left in the press from a previous push and the slugs loaded into the mud chamber for the succeeding push. Examples of these are shown by carbons 1, 2 and 6.

Enlarged Ends. As arranged in Fig. 21 the enlarged ends of the carbons are at the top. It is probable that the enlarged end is of low density and that the ends of the carbon are of unequal density and porosity. These carbons would give difficulty in loading and unloading in the baking furnaces.

Oval Ends. The ends of the carbons shown in Fig. 21 "C" have been mashed by the knife in cutting. Because of their badly shaped ends they would give difficulties in baking as far as loading and unloading in the furnaces is concerned and would give poorer results in use.

Blisters. Blistering may be due to excessive friction between the carbon stream and the die, or else the building up of too high a local temperature under the die when the stream is stopped. The volatile portions of the binder begin to distill and form gas bubbles under the skin of the carbons. As the gases expand, they cause the bubbles to grow larger and finally break. Blistering occurs as the carbons are extruded and released from the pressure of the die. Another theory is that blisters are caused by imprisoned air in the slugs, due to slugs being too tight a fit to press chamber and not permitting air to escape when loading. Blistered carbons are shown in Fig. 22.

Cross Checks. It is not easy to see the defects in carbons 1, 2, 3 and 4 of Fig. 23. The cross check in 1 is near the top of the carbon; in 2, 3 and 4, it is nearer the middle. Cross checks are weak sections. They might be termed lines or planes of breakage. In baking, cleaning or handling these carbons will invariably break at the cross check.

After the electrodes have been inspected and those of the defective types just described have been eliminated, the sound, well-shaped electrodes are piled on trucks, weighed and sent to the baking furnaces. Samples of each lot are taken for density determination and chemical analysis.

Editor's Note. The next article of this series, which will be the baking process and the equipment used therein, will appear in a subsequent issue.

Verifying the Elastic Limit

The French Committee on Standardization authorizes the following method for verifying a supposed elastic limit: "The gaged test-piece is subjected to a quiescent load specified as the elastic limit, and on releasing the load no permanent set must have taken place."

Equipment Used in Petroleum Refining

Chemical equipment manufacturers will be interested in the results of the detailed study of statistical returns made by the petroleum industry in connection with the fourteenth census of manufactures. In the report just issued by the Bureau of the Census a tabular comparison is made of equipment, such as stills, agitators, storage tanks, etc., used in petroleum refining. These statistics are compared with those of the preceding census (1914) in the table which follows:

Kind	1919	1914

Z-Transformations in Iron

If a rod of uniform wrought iron be cut into small pieces, each one quenched from a series of successively higher temperatures from 100 to 1,000 deg. C., and its thermal e.m.f. compared against an untreated piece, a curve may be drawn which will not only show the well-known A_1, A_2 and A_3 transformations, but twelve others. The unknown points are called Z-transformations by Prof. G. Borelius of the University of Lund, Sweden (*Annalen der Physik,* vol. 67, p. 227). These irregularities do not occur in pure electrolytic iron fused in vacuo, but reappear and grow in intensity with extended annealings in hydrogen. They may be related to the discontinuous liberation of hydrogen below the critical ranges which are held responsible for the small liberations of heat first observed in thermal analysis of iron by Roberts Austin. Quenching seems to be essential to the Z-effect, and Dr. Borelius concludes they are due to carbon or hydrogen, or other impurities (but not silicon).

Etching of Aluminum Bronze

It is particularly difficult to develop the structure of aluminum bronze (92:8 Cu:Al), especially in the form of rolled and annealed sheet. Rawdon and Lorentz, in Scientific Paper 435 of the Bureau of Standards, note that in a score of comparative etchings the best results by far are had by bubbling oxygen through concentrated ammonia. By this means the boundaries of the crystals are clearly outlined, with a considerable contrast between the different crystals. Cast aluminum bronze will show excellent contrast after 20 seconds in a 10 to 1 mixture of concentrated NH_4OH and 3 per cent H_2O_2 or 5 seconds in concentrated HNO_3.

Black Fractures in Carbon Tool Steels

Occasionally All Bars From a Certain Crucible Steel Ingot Will Show Black Centers When Fractured on Final Inspection — Black Masses Machine Like Cast Iron but Become File Hard on Normal Quenching, Yet Return After Reannealing

By Arthur W. F. Green
The John Illingworth Steel Co., Frankford, Philadelphia, Pa.

IT IS not an uncommon thing to go into metallurgical laboratories and hear the various "ites" which are found in steel and iron referred to as "animals." Occasionally one hears that a new "animal" has come into being, and then everyone is set to work trying to find whether or not it had been seen before, and if so, what the technical name of it may be, or else they give it a suitable name and otherwise designate it so that it will be immediately recognized when seen again. It is the purpose of this note to show an "animal" which has been seen on a few occasions in this laboratory, but to the best of my knowledge has not been named or otherwise definitely identified.

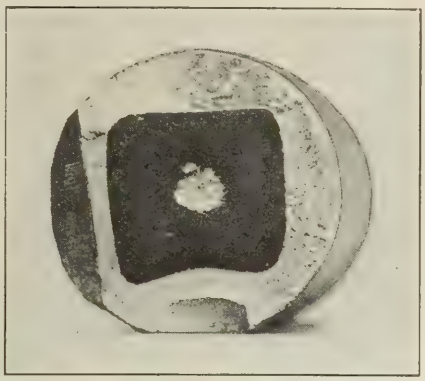

FIG. 1—FRACTURE OF TOOL STEEL WITH BLACK CENTER

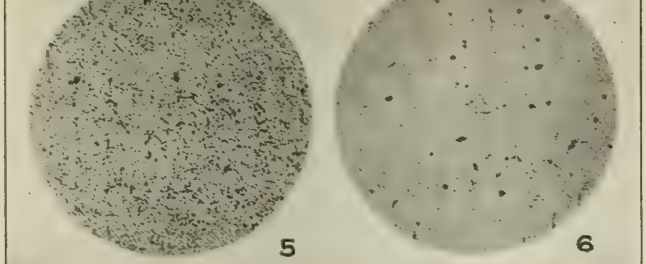
The particular "animal" in question has been noted only in hyper-eutectoid steel made by the crucible process and only in straight carbon tool steel. It is seen by the unaided eye as a mossy, solid black constituent. A definite idea of the material and the well-defined area which it may occupy is seen in Fig. 1. This represents a section taken from a bar of 1⅛ in. diameter. The same condition existed in the several bars coming from one 100-lb. ingot. None other appeared in several weeks' or months' production. The chemical analysis was in no way unusual or deviated from that aimed at, which was: C 1.16, Mn 0.30, P 0.024, S 0.02 and Si 0.25 per cent. Samples have later been found in which the entire section of the bar has been black in fracture, with the exception of a small area about ¼ in. in diameter in the center, and a ring about 1/16 in. around the outside. Other samples have been found in which only small black areas have been noted, as for instance, in a 2-in. round, in which several well-defined squares were distinguished, one inside of the other, the largest about ¾ in. square and the smallest about ¼ in. In all cases the blackened areas are symmetrical about the axis of the bar, and conform in shape to the outline of the ingot, billet or bar at same stage in its manufacture.

These black areas have never been noted except in steel after it had been annealed and in which complete spheroidization of the cementite in the unaffected areas had taken place (a structure, it may be remarked in passing, which we consider most desirable for carbon tool steels). On one or two occasions it has been found that the steel was permitted to remain in the reheating furnace at rolling temperatures for a longer time than necessary, so that the square-shaped areas usually noted may be the result of conditions caused by that circumstance. However, it is not until the bars have been annealed, as before stated, that the black areas become noticeable. The temperatures employed for annealing were always about 1,300 to 1,350 deg. F. or just under the $Ac_{1,2,3}$ range, as evidenced by the complete spheroidization of the cementite in the unaffected areas. Annealing is done with careful pyrometric control in large modern furnaces, holding about 7 or 8 tons per charge. Only occasionally will two or three bars from a certain ingot emerge with this defect. It is discovered in the inspection, since each bar is nicked, broken, and the fracture examined before it is sent out on order.

Chemical analyses have been made of both the black portions and the light ones in the same bar, but no differences have been noted in carbon content or otherwise. The sample depicted in Fig. 1 showed 1.16 per cent carbon throughout. When the dark portions are

FIGS. 2 TO 4—MICROSTRUCTURE, ETCHED WITH PICRIC ACID. × 100
FIG. 2—Transverse section at junction. FIG. 3—Longitudinal section at junction. Fig. 4—Longitudinal section in black mass.



FIGS. 5 AND 6—MICROSTRUCTURE ETCHED WITH SODIUM PICRATE. × 100

Fig. 5—Normal structure of steel.
Fig. 6—Longitudinal section in black mass.

machined they give off identically the same kind and color chips as does high-grade gray cast iron. The black areas are also much softer in the annealed steel than are the good ones (Brinell 95 against 170). When the material is ground on an emery wheel, no difference is noted in the sparking between the good areas and the black ones, both giving off the characteristic sparks of a hyper-eutectoid steel of the same analysis.

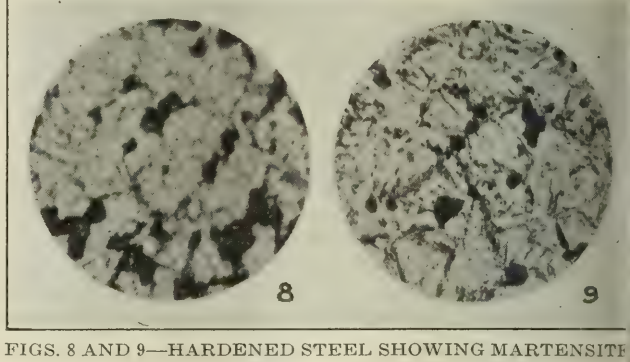
Microscopic study of the material shows some interesting conditions as seen by referring to the accompanying photomicrographs. Fig. 2 represents a section of the material at the sharp junction between the good and the blackened areas. The cementite is spheroidized in those areas which do not appear black to the unaided eye. You will also note that the other portion which appears black to the unaided eye shows microscopically somewhat as a low-carbon steel. This photomicrograph was made from a transverse section. In Fig. 3 is shown

FIG. 7—HEATING AND COOLING CURVE OF SAMPLE CUT FROM BLACK MASS

a portion of the same sample in a position approximate to that shown in Fig. 2, but here the material was cut longitudinally, and the etching is slightly deeper. Fig. 4 shows a lightly etched section of the black area in longitudinal section, and attention is especially called to the free iron areas and the dark network in the etched portions.

Some of the material was etched in boiling sodium picrate solution to ascertain whether any free cementite occurred in the blackened areas. The results of this treatment on the good portions are shown in Fig. 5, conclusively proving the existence of spheroidized cementite. Fig. 6 shows the effects of the same etching on the blackened parts. Here will be noted the large black dots which appear in the free iron and in the slightly darkened areas. The latter may be made up of finely spheroidized cementite.

It was at first believed that the black material would not harden, especially because the manner in which it machined suggested that it was full of graphite. In



FIGS. 8 AND 9—HARDENED STEEL SHOWING MARTENSITE AND TROOSTITE, ETCHED WITH PICRIC ACID. × 500

Fig. 8—Spheroidized cementite after hardening.
Fig. 9—Black mass after hardening.

order to get as much information about the hardening as possible, a sample was carefully machined from the blackened portion of a sample and critical points obtained therefrom. The curves are shown in Fig. 7 and are no different than those of a usual hypereutectoid steel of 1.10 to 1.20 per cent carbon. Several pieces were then taken from bars containing some of the blackened material and heated to an indicated furnace temperature of 1,420 deg. F. One was quenched in water, and two were quenched in brine from the indicated temperature. All of the samples were file hard throughout. The microstructure of one of the brine-quenched pieces is shown in the photomicrographs, Figs. 8 and 9. The piece shown in Fig. 8 was taken from a section of the good portion, while that shown in Fig. 9 was taken from the blackened area.

After the pieces had been hardened, two were taken and annealed. The first was heated to 1,400 deg. and held for 3 hours, then slow-cooled in the furnace. The second was heated to 1,320 deg. F. for 2 hours and slow-cooled in the furnace. In the first piece the original black areas returned and the good portion showed no difference from the original, but in the second piece it was noted that parts of the original good areas had started to become black. This would seem to show that the low-temperature annealing further the promotion of this blackened material.

The present writer has speculated upon the origin of this structure, but has not been able to formulate a hypothesis which explains all the facts. Therefore

e effort has been made to give the facts about the nimal" exactly as they have been found, hoping that may excite some criticism and possibly argument. thers may be able to identify and name the black nimal" from these notes, or present a plausible theory the cause or causes for its existence. We also have few bar-fragments on hand which are available to etallurgists who wish to study the phenomenon at st hand.

The Utilization of Waste Heat*

GREAT progress has been made in recent years in the development of methods of utilizing heat, especially in the steel and cement industries, and serving region in which these products are extensively manufactured, the Lehigh Valley section of the A.S.M.E. appropriately devoted a recent meeting held at Bethlehem, Pa., to a consideration of this subject. Three papers were presented: "Waste-Heat Boilers," by B. Smith, of the Babcock & Wilcox Co., New York, Y.; "Utilization of Waste Heat in the Steel Industry," by A. T. Lewis, of the Bethlehem Steel Co., Bethlehem, Pa.; and "The Utilization of Waste Heat From otary Cement Kilns," by Joseph Brobston, vice-president, Dexter Portland Cement Co., Nazareth, Pa.

The Application and Performance of Waste-Heat Boilers

The Babcock and Wilcox Co. has at the present time stalled and in operation, in connection with the various types of industrial furnaces, waste-heat boilers of total capacity of 153,499 rated boiler horsepower, stributed as follows:

pen-hearth furnaces..	102,211	Glass tanks.....	1,716
ment kilns.....	15,834	Copper-refining furnaces..	1,347
ehive coke ovens....	11,730	Nickel furnaces.....	922
nc furnaces.....	8,740	Lime and dolomite furnaces	848
eating furnaces (various types).....	4,243	Malleable-iron furnaces..	373
l stills.....	3,975	Silicate furnaces.....	232
as benches.....	1,328		

The flues and valves connecting the furnace and the aste-heat boiler must be of such construction that the r infiltration and radiation may be kept at a minium. Very little difficulty is found with radiation sses, but the air infiltration in every plant is, without xception, a difficult problem. Of course, it is possible install a fan and fan turbine of sufficient size and pacity to overcome all of the air infiltration, but if is is done the net steam output of the installation ay be reduced to such a point that the return will not arrant the investment.

Draft and the resistance of the gases passing through boiler are two of the important factors in waste-heat stallation design. The draft loss is a function of two ctors—the loss due to frictional resistance and the ss due to the passage of gases over and under the affles. In order to obtain the greatest net amount of eam from the boiler, the draft required at the entance to the boiler and the draft loss through the boiler hould be so proportioned that when a steam turbine of inimum water rate for this class of machine is used drive the fan, the exhaust steam from this turbine ill not be greater than can be absorbed by the water heating all the water consumed by the boiler to 10 deg. F. With such an arrangement there is a ermal loss which, when expressed in boiler horsepower, will be approximately 2 per cent of that generated by the boiler.

Failures Due to Lack of Attention

"Because of the war" is an expression much used when citing causes for trouble and sometimes failure, and to this same cause can be attributed in a large measure the failure of some of the users of waste-heat boilers to give proper attention to the upkeep of their installations. This failure has come through the abnormal drive for output which has affected not only the waste-heat-boiler installations but the apparatus of the entire industrial plant as well. Another thing which has contributed to the inadequate attention has been unreliability of the labor obtainable.

Upkeep Costs Low

There is every reason to believe that the upkeep costs of waste-heat installations are very low, for, taking them as a whole, it will be agreed that because of the low-temperature gases which are encountered the tube losses from blisters will be rendered practically negligible, if not impossible. These low-temperature gases also result in a minimum brick deterioration, and in practically all cases the brick replacement cost should also be negligible. The only class of waste-heat work where brickwork upkeep cost need be considered is in the open-hearth field. While there are systems of reversing valves which entirely eliminate the possibility of explosions in open-hearth waste-heat work, the use of such systems is not general, and with the valve reversing systems in common use it is practically impossible to prevent an occasional explosion. These explosions vary in intensity and have under certain conditions been sufficiently severe to blow out the side boiler wall, and in one instance to break off the header doors from the hinges.

Types of Boilers Used in Steel Works

The simplest form of Babcock & Wilcox waste-heat boiler offered is of the single-pass short-tube type, usually 9 to 11 ft. in length and 27 tubes high with a stack located on top of the boiler setting. This type of boiler is particularly applicable to furnaces requiring a low draft for operation and high gas temperatures as the gases leave the furnace. By high gas temperature is meant a temperature considerably in excess of that encountered in open-hearth and cement work, yet below that encountered in coal- and oil-fired furnaces. It does not follow, however, that such a boiler could not be used with temperatures from 2,500 to 3,000 deg. F., for with these temperatures and the very low draft required the boiler would show a high efficiency.

The typical Babcock & Wilcox waste-heat boiler for open-hearth furnace work is an 18-high cross-drum, usually with 16-ft. tubes, the gases being delivered to the fan through the horizontal circulating tubes. The fan, gears and turbine are supported on a platform above the boiler carried on the boiler columns.

The majority of installations with open-hearth furnaces have been in mills already in operation, and oftentimes it has been no little problem to find a space large enough to install a boiler of the proper heating surface. The sectional design of the B. & W. boiler, however, has been of advantage in such cases, for with this it is possible to modify the width, length and sometimes the height to accommodate the local space conditions and thereby provide a sufficient and efficient heating surface.

*Abstracted from *Mechanical Engineering* for August, 1922.

The returns from such installations have been most gratifying. Not only has there been a return in steam sufficient to pay a handsome return on the investment, but in many of the plants there has been an increase of two heats a week from the open-hearth furnaces accompanied by an appreciable reduction in the coal per ton of steel. This reduction follows from a positive draft control.

Figures given during the war indicated a saving due to the installation of waste-heat boilers on open-hearth furnaces of from 25 to 30 cents per ton of steel produced. On the basis of 25 cents a ton, 50-ton heats and fourteen heats a week for 45 weeks, the annual saving would amount to $8,400, while for a 100-ton furnace it would be $16,800. With a 100-ton furnace there would be offered a boiler of 550 hp., which at the period mentioned could be installed complete for approximately $50 per horsepower, or $27,500. On such a basis the installation would pay for itself well within 2 years.

In a representative arrangement such as would be made with a malleable-iron furnace the boiler employed is 24-high, three-pass, with longitudinal drums, the draft apparatus being located on a platform carried on the boiler columns. The unit is equipped with an auxiliary hand-fired furnace, which makes possible steam generation during such times as the malleable-iron furnace may be shut down. It is possible, however, to operate the boiler on both waste gases and gases from the hand-fired furnace, due to the fact that the draft required to operate the malleable furnace is about the same as that which would be required for hand firing.

Installations in Cement Mills

In 1915 a 1,530-hp. Babcock & Wilcox boiler was installed for the Louisville Cement Co., this company being really the pioneer in the use of the modern design of waste-heat boiler in connection with cement kilns. Regarding the operation of this boiler, H. D. Baylor, superintendent of the company, in a paper presented before the American Institute of Chemical Engineers in June, 1917, said:

> Our coal consumption in the boiler room for 1914 averaged 91.7 lb. per barrel of cement. The waste-heat boiler was put into service during May, 1915, with the result that our average coal consumption for 1915 was 57.6 lb. per barrel of cement. During 1916 the boiler was operated practically full time and our average fuel in the boiler room for the year was 40.2 lb. per barrel.
>
> By using the hot clinker to heat the air for combustion and the waste kiln gases to generate steam, our percentage of heat utilized has almost doubled, showing 67.2 per cent fuel efficiency in the combined system of kilns and waste-heat boiler, and this we hope to increase to 70 per cent by reclaiming a part of the heat now lost by radiation from the kiln shell; and it is but another step to reclaim a part of the heat now escaping from the stack of the waste-heat boiler; or in other words, our combustion efficiency will eventually compare very favorably with general boiler-room efficiency.

In one standard arrangement of waste-heat boilers, economizers, fans, collecting and connecting flues for cement-kiln work there is a common flue located transversely to the kilns into which they deliver the gases. On the opposite side of this flue the boilers are located, the gases passing through the short connecting flues. Between the kilns and the collecting flues, as well as between the collecting flue and the boilers, water-cooled dampers are provided. The bottom of the flue is a series of hoppers for depositing and handling the dust precipitated from the gases. These hoppers are provided with a slide valve and chute for discharging the dust to screw conveyors located beneath the main flue. The boilers, economizers and all short connecting flues are also provided with hoppers similarly equipped with slide valves and chutes. The main flue and all connecting flues are made of steel plate lined with insulating material and firebrick.

An arrangement of this kind lends itself to flexibility in that any boiler or kilns may be taken off without interruption of the plant output, since the boilers are so designed, when there are three or more, that one boiler may be taken out of service and the remaining boilers handle all of the gases. When an installation of only two boilers is made it is not practicable, from the standpoint of cost, to have each unit of sufficient size to handle the total weight of gas, should it be necessary to take one unit off the line. A two-unit installation is therefore not as flexible as one with a greater number of boilers, and with one unit down, the remaining unit, while capable of handling more than half the total gas, would probably not handle more than 75 per cent of the total, necessitating the bypassing of the remaining gas to the atmosphere.

The economizer employed is of the counterflow type. The tubes are inclined horizontally, extending transversely to the boiler tubes. The gases pass downward over the heating surface, thereby reducing the tendency of dust to settle and lodge on top of the tubes. The water flows upward, thereby avoiding pockets should any steam be formed in the economizer.

These boilers and economizers are provided with a type of soot blower which, if properly operated and properly cared for, will keep the gas passages entirely free from dust lodging, so that it hardly becomes necessary to shut down a boiler for external cleaning.

The fan location is at the floor line and a steel stack is carried on the fan housing. The stack should be of sufficient height to relieve the fan of labor in discharging the gases. It should also be of sufficient height to guard against the gases entering adjoining buildings as they leave the stack.

Utilization of Waste Heat in the Steel Industry

The operations of the steel industry are such that very large quantities of heat are necessary to perform the desired work. Only a small part is being converted into useful work, which leaves a large per cent of energy in the form of waste heat.

Blast Furnaces

Most steel plants are equipped with blast furnaces, open-hearth furnaces, mills, forge and machine shops, power plants and buildings, and they are usually so grouped that the utilization of heat in any branch can be converted into work of benefit to the other departments.

In blast-furnace work the gas was considered a waste product a short time back, and still in many furnaces this valuable fuel is bled to the atmosphere. Even in many modern blast-furnace plants a great improvement can be accomplished in its better utilization. This gas is primarily used for stoves, blowing and power engines, boilers and miscellaneous heating. With properly designed equipment and proper control the maximum economy should be obtained, and the quantities are so large that such economy would spell great savings.

A blast-furnace heat balance shows that approximately 40 per cent of the heat available in the furnace

used in its own operation. This includes preheating f the air and the losses carried away from the furnace nd leaves 60 per cent available for other useful work, uch as power units, boilers and miscellaneous heating. o realize the importance of the proper utilization of his waste gas an approximate heat balance of a 500- on blast furnace is given in Table I.

Open-Hearth Furnaces

The highest temperature that can be obtained from uel is desired in the refining of steel. For this rocess a relatively small percentage of the available eat of the fuel is abstracted, which leaves a very igh percentage to pass out from the furnace. A small art of this heat leaving the furnace is recovered in he preheating of the incoming air and gas. In a 70-ton pen-hearth furnace from 70,000 to 100,000 lb. of gas ormally enters the stack per hour at a temperature f from 1,000 to 1,200 deg. F., and this heat should e utilized. The steel mill usually requires a large eneration of steam. The utilization of this heat by eans of waste-heat boilers is a means of reducing con- iderably the total steam-generating costs.

The fuel usually employed is producer gas, unless oke-oven or natural gases—of higher calorific value— re available. In order to develop the necessary tem- erature and also to effect economy of fuel the air for ombustion is preheated before entering the furnace. Where the more sluggish producer gas is used, it is lso preheated, which enables it to ignite more readily han when cold. When coke-oven or natural gas is sed it is introduced into the furnace without pre- eating because both are high in hydrocarbons which isintegrate at temperatures above 1,000 deg. F. hereby causing great fuel loss. In the average open- earth furnace it will be well to note that of the heat bsorbed and the heat that is available for waste heat evelopment—

18 per cent is abstracted for useful work
3 per cent is lost in the sensible heat of the slag
40 per cent is lost in the sensible heat of the stack gases, and
39 per cent represents other losses such as radiation, etc.

The largest item is the heat lost to the stack, and n many furnaces this amounts to more than 50 per ent. To reduce it the steel plants have resorted to vaste-heat boilers by means of which about 50 per cent f the loss can be converted into steam. Furnace gases normally enter the boiler at from 1,000 to 1,200 deg. F. nd are reduced to a temperature of from 450 to 550 eg. F. before leaving. A well-designed boiler equip- ment with necessary flues is an asset in the operation of a furnace, since the draft may be regulated by the fan speed at the will of the furnace operator. Furthermore, the value of this abstracted heat is equivalent to 60 boiler horsepower per ton of steel. This is equivalent to at least 350 boiler horsepower per furnace of about 70 tons capacity and is valued at $3.50 per hour, using anthracite steam coal at $3 per ton as a basis for calculation. It amounts to $2,500 a year per furnace and is the best way of recovering heat energy that would otherwise be lost at certain times in metallurgical processes.

Mill heating furnaces have a lower exit temperature than open-hearth furnaces, and if the proper state of combustion is maintained and the furnace is designed correctly a higher thermal efficiency should result. The exit temperatures of mill furnaces vary from 850 to 2,000 deg. F., and the quantity of heat generated is dependent upon the capacity of the furnace. A waste-heat boiler installation on such furnaces makes an ideal layout and fits in nicely with the steel-mill boiler plant. Table II shows a typical heat balance of an open-hearth furnace including waste-heat boiler.

TABLE II—TYPICAL HEAT BALANCE OF AN OPEN-HEARTH FURNACE INCLUDING WASTE-HEAT BOILER*

	B.t.u. Per Hour	B.t.u. Per Ton Ingots	Per Cent of Heat in Coal	Per Cent of Heat in Fuel Gas	Per Cent of Heat to Furnace
Coal to gas producers	52,500,000	7,000,000	100.0	.....	.....
Producer loss	8,610,000	1,150,000	16.4	.....	.....
Heat delivered to furnace:					
Gas from producers	43,890,000	5,850,000	83.6	100.0	.....
Combustion of C, Si, and Mn in charge	9,370,000	1,250,000	17.8	21.4	.....
Sensible heat of hot metal	3,450,000	460,000	6.6	7.9	.....
Total heat to furnace except regenerated gas and air	56,710,000	7,560,000	108.0	129.3	100.0
Distribution of heat:					
Consumed in furnace and losses	31,450,000	4,192,000	59.9	71.8	55.5
Utilized in boiler	15,510,000	2,068,000	29.5	35.3	27.3
Wasted to stack at 500 deg. F.	9,750,000	1,300,000	18.6	22.2	17.2
Total	56,710,000	7,560,000	108.0	129.3	100.0

*Results based on the following empirical data:

Size of heats, tons	75
Time per heat, hours	10
Hot metal in charge, per cent	64
Ratio of product to charge, per cent	88
Fuel consumption (4,875 lb. per hr. or) lb. per ton	650
Heat value of coal, B.t.u. per lb.	10,700
Weight waste gases at boiler, lb. per hour	81,400
CO_2 in waste gases at boiler, per cent	12
Temperature of waste gases at boiler inlet, deg. F.	1,200
Temperature of waste gases to stack deg. F.	500
Performance of boiler under above conditions, boiler hp	460

Gas Versus Steam Power

Modern steel plants that have blast furnaces are usually equipped with gas-engine installations. Gas engines have shown marked improvement in recent years and are employed on account of the low total cost of operation, which is particularly true in the blowing units. This is caused by their relatively high efficiency when compared to steam units.

It will be well to consider the percentage heat balance of a gas engine and compare it to that of a steam engine as follows:

	Gas Engine	Steam Engine
Effective work	28	11
Friction in engine	5	2
Exhaust gases	36	..
Exhaust steam	..	57
Cooling water and radiation	31	..
Boiler loss	..	30
	100	100

The total gas-engine efficiency can be raised to above 60 per cent, which establishes it as a most economical

thermal unit. The development of waste-heat utilization in gas-engine installations should create a greater demand for this type of prime mover in the future, and it will show up to better advantage as the price of fuels increases. A very high efficiency is readily obtained by installing waste-heat boilers or economizers in the gas-engine exhaust and utilizing the jacket water either for feedwater, heating buildings, or any other scheme that will fit into plant conditions.

Utilization of Waste Heat From Rotary Cement Kilns

In America, portland cement is burned exclusively in what is known as a rotary kiln. This is strictly an American development. It has always been known that it was not an economical method of burning, but as coal was cheap and labor high in America, it was universally adopted immediately after its introduction, whereas in Europe, where coal was dear and labor cheap, the old style upright kiln similar to a limekiln held its own up to within a few years.

While the largest loss of heat in the rotary kiln was in the excessive temperatures of the flue gases, there were two other important heat losses which were at that time attracting attention, one being the heat carried off by the material or resulting clinker, when it was discharged from the kiln; the other being the loss by radiation through the kiln shell.

There was one notably successful attempt made to utilize a part of the heat of the flue gases. In the dry process of cement manufacture it is necessary to dry the raw material before it can be pulverized. Charles Matcham put his stone driers immediately back of his kilns, and passed a portion of his kiln gases through them. This did not affect the operation of his kilns, dried the stone more effectively, saved about 3 to 4 lb. of coal per barrel of cement made and materially reduced the labor charge in connection with the drying. Only a small percentage of the total stack gases were required for this, however, and there were not many of the installations made.

Money Saved From Waste-Heat Utilization

The sporadic efforts made to use the waste heat of rotary kilns prior to the sudden and material increase in the price of coal caused by the war did not amount to more because of the very low price that the industry as a whole paid for its kiln coal. The coal generally used is the slack or screenings from three-quarter gas coal. This was formerly considered a waste product by the coal mines and had to be moved when the three-quarter coal was shipped, which resulted in a price to the cement industry ranging from 20 to 75 cents a ton at the mines. The cost per barrel for burning cement was therefore comparatively low and the efforts of the manufacturers were mainly directed to installing labor-saving machinery and reducing the cost of pulverizing the raw material and clinker.

When the price of coal jumped to $5 per ton at the mines, however, conditions were entirely different, and in 1915 the first modern waste-heat boiler plant in the cement industry was installed at the Catskill plant of the Alpha Portland Cement Co. This installation was a success from the start. The plant operates five kilns, three being 9 ft. in diameter by 120 ft. long and the other two 7 ft. 6 in. in diameter and 120 ft. in length, resulting in an output of about 3,000 bbl. of cement per day. The gases from these kilns are drawn into a main or equalizing flue directly in the rear of the kiln housing or dust chamber, dampers being installed to bypass gases into the kiln stacks, if necessary. Connections leading from the back of this flue conduct the gases to two 750-hp. Edge Moor boilers, of the four-pass type. Two Green fuel economizers, horizontal type, are installed after the boilers.

The forced draft is provided by a fan located directly back of the economizers, driven by a Terry turbine. A steam pressure of 175 to 180 lb. is maintained, and sufficient power is generated to operate the entire plant. The finely pulverized stone carried over from the kiln by the hot gases is blown from the boiler tubes three to four times in each 24 hours, a hand lance using 140 lb. of air being employed for this purpose. The economizer tubes are blown off through plugged openings in the top of the casing several times each week. The clean-out doors at the bottom of each pass are opened once a week and the dust removed. Clean-out doors are also provided in the flues. In this way, if the draft at the stack chamber is not allowed to drop below 0.25 in. (water pressure), no real difficulty is experienced in keeping the installation free from dust. The temperature of the gases is reduced from approximately 1,400 deg. F. at the mouth of the kiln to about 450 deg. when they leave the economizer. The Cochran feedwater heater is heated by the exhaust steam from the pumps and fan turbine.

Coal Savings From Waste-Heat Utilization

The operation of the boilers has not increased the amount of coal used per barrel in the kilns. It is about 95 lb. per barrel. It requires not less than 40 lb. of coal per barrel to generate the power required to operate a cement mill. Deducting this from the 95 lb. being used in the kiln we find that today this company is burning its cement with 55 lb. of coal, which is much closer to the theoretical amount required—that is, 30 lb.—than the cement manufacturers had ever hoped to come, and means that a rotary kiln with a waste-heat boiler attached is as economical in its coal consumption as the old-style upright kiln. Plants almost exactly duplicating the one described were promptly installed at another plant of the Alpha Portland Cement Co. and at the Dexter Portland Cement Co., and plants using B. & W. boilers were installed by the Universal and Louisville cement plants.

By this time all the manufacturers of portland cement were aware of the importance of this development, and the conservation committee of the Portland Cement Association started an extensive investigation of the entire question. The first report, presented in December, 1918, showed eight plants in operation. Today there are twenty-four plants in operation generating with their flue gases from 51 to 140 per cent of the power they require. There are about 120 operating portland cement plants in the United States, so that 20 per cent of the plants are now making use of their stack gases, saving on the average 40 lb. of coal for every barrel made. This means that these companies are actually using about 400,000 tons of coal less per year than they did formerly.

It may be noted that in some cases more steam than is required to operate the entire cement plant is gen-

rated by the waste-heat installation. In other cases nly a little over one-half of the amount required is ecured.

While this is to a certain extent a question of the fficiency of the boiler installation, it may be due to ther causes. The plant that is burning cement with 0 lb. of coal to the barrel will not have the volume of tack gases or temperature that will be found at the lant using over 100 lb. to the barrel, so that naturally ot as much steam can be generated. The total amount f coal used per barrel, however, may be lower at the lant using the 80 lb., as it may be possible to gen- rate the additional power required in auxiliary boilers ith less than the extra 25 or 30 lb. of coal consumed n the kiln.

But even when two waste-heat plants generate the ame amount of steam, there may be a great difference n the percentage of the machinery that can be run with . Where the amount of steam secured is just sufficient o operate a mill in which the prime movers are well- esigned modern turbines, it would probably be only 5 per cent of the steam required to operate another lant which is still being run with old-style inefficient eciprocating engines.

Power Required to Grind a Barrel of Cement

Where the prime movers are identical, there might ill be a wide difference in the percentage shown. ecent investigations show that the power required to roduce a barrel of cement at plants using different ypes of grinding machinery varies from about 13 w.-hr. per barrel to about 19 kw.-hr.

Some progress has also been made in the last three r four years in solving two other problems. The loss through radiation is being materially reduced by put- ting between the shell and the firebrick lining in the upper part of the kiln, a brick cut from diatomaceous earth. While it has not been possible to determine the exact amount saved in this way, it has been shown conclusively that where waste-heat boilers are being used this installation raises the temperature of the flue gases 150 deg., and where boilers are not installed the insulated kilns require from 5 to 10 lb. per barrel less coal to burn clinker than those not insulated.

This problem is not as yet fully solved, however, as it has been found impossible to use the insulating brick in the hottest section of the kiln, known as the burning zone. Here the fluxing action of the clinker at the high temperature necessarily maintained was such that the firebrick were practically destroyed in from 16 hours to four days. The hot zone can un- doubtedly be insulated by using carborundum, but at the present time the cost of doing this would be prohibitive.

Possibility of Reclaiming Heat Carried Off by Clinker

As to the possibility of reclaiming the heat carried off by the clinker, the development of the rotary pres- sure cooler in the last few years has demonstrated that where the cooler is of sufficient size and proper design to handle the kiln output it is possible to heat the air entering the kiln to a temperature of 800 to 900 deg. F. and to have enough heat left over to dry the coal used for kiln operation. How much this saves is problematical. So far the power required to operate the system has been found to be so great that there appears to be very little actual saving.

Synopsis of Recent Chemical & Metallurgical Literature

Prism Hardness

A prize was awarded in the fall of 920 to Dr. Bernard P. Haigh of the oyal Naval College, Greenwich, Eng- nd, by the Institution of Mechanical ngineers for a method of determining ne hardness of excessively hard steels. also appears to be capable of con- stent results on metals as soft as an- ealed copper.

Briefly, the method consists in cross- ng two finished bars of the material to e tested and pressing them together ith a known force, P. The width of ne resulting notch or indentation, w, then measured with a microvernier, hereupon the "Prism Hardness" quals $P \div w^2$. In practice it is handy o use the fragments of an impact test, olding them in place in a jig and ressing them slowly together in a rinell machine or small testing ma- nine.

Sharp edges are necessary only on ne hardest metals. Tooled or rough round surfaces are sufficiently smooth, xcept for glass hard specimens. Pro- ided the faces are reasonably plane nd the width rather than the depth f indentation is measured, it is not es- ential that the angle should be exactly 0 deg.

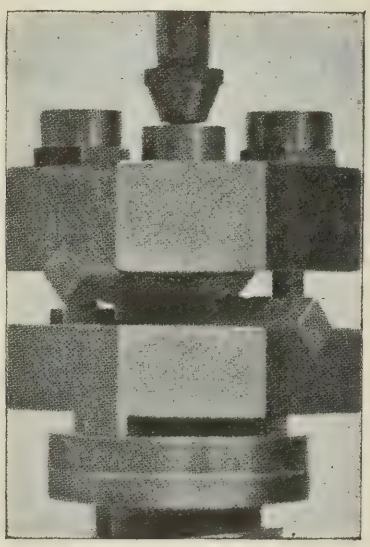

FIG. 1—JIG WITH CROSSED PRISMS IN PLACE

Prism hardness. $P \div w^2$, is remark- ably constant with varying loads, as long as the width of indentation is less than half the side of the prism (in soft metals), or no splintering occurs (in hard metals). The tests in the foregoing table on a good 60: 39: 1 naval brass are illustrative.

Prism Hardness — Load (Long Tons)	Hardness	Brinell Hardness — Load Pounds	Hardness (10 mm. Ball)
1	36.5	200	63
2	35.8	600	78
3	35.3	1,000	79
4	34.8	2,000	89
5	33.5	3,000	87
..	..	4,000	90.5
..	..	5,000	92
..	..	6,000	93

Results derived from a series of tests on 4 hardened carbon steel knife edges are as follows:

Load in Long Tons	Prism Hardness — A	B	C	D
¼	...	...	359	388
½	282	403	357	358
¾	288	..	354	...
1	298	392	359	376
1¼	293	..	345	..
1½	289	382	S	393
1¾	...	..	...	387
2	294	380	..	S
3	287	373	...	...
4	283	378	...	...
5	287	387	...	...

Sample A appears to be incompletely hardened. B is harder than the ball steel usually used in the Brinell test. (Prism hardness 318 tons per sq.in.). Sample C was rejected at the works for brittleness and splintering occurred under loads of 1½ tons or greater. Sample D was rejected for water cracks and splintered at a 2-ton load. "The hardness values do not vary with load more widely than may be attrib- uted to experimental variance or slight changes in structure, and may be regarded as independent of the load applied in making the test."

"The test has proved sensitive to slight differences of hardness, even in the hardest metals."

Loam Molding as an Art

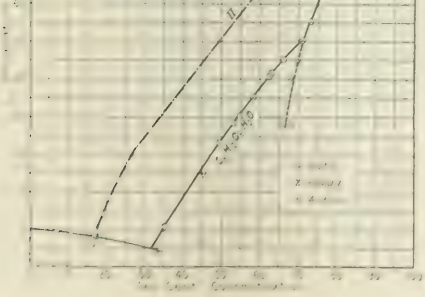
A "History of Loam Molding in the Province of Liége" was presented to the Institution of British Foundrymen at their Birmingham meeting, 1922, by J. Varlet. In a few pages, the author traces the development of the process from the first attempts of a patternmaker named Pirson in 1846, its general adoption by Belgian foundries in 1870, through the period of its greatest perfection (1890-95) to the present practice. Modern methods of molding large cylindrical or conical castings like slag pots or sugar cane colanders and more complex things like flywheels and marine engine cylinders are given in detail.

About 30 years ago a man could not claim to be a loam molder unless he had served his apprenticeship as a core maker, had then studied mechanical drawing and machine design so as to be able to read blue-prints with great facility and understand the function of all common machine units, and finally had served a long second apprenticeship to a leading molder. "He worked with his hands in the foundry and his head at home. Every night he organized his work for the next day. He was animated by a sincere love for his profession; he had the respect of his chiefs; he respected himself, and, above all, he conducted himself as an artisan of an intellectual profession, who had the right to everyone's consideration."

Nothwithstanding the fact that the general appearance and skin of loam castings are much superior to sand castings, the method is not used as much now as formerly, according to the author, because of the disappearance of the long-stroke, low-pressure or slow-speed steam engine.

The Solubility of Dextrose in Water

A recent publication from the Bureau of Standards, No. 437, dated February, 1922, deals with the determination of the solubility of dextrose in water, and of the various solid phases which can exist, including the range during which those phases are stable. The authors, Richard F. Jackson and Clara Gillis Silsbee, have made a really valuable contribution to industrial work with this substance, because the solubilities are of fundamental importance in controlling the processes of manufacture. They found, among other things, that the temperature coefficience of solubility was much higher with the dextrose hydrate, which has a transition point at 50 deg., than it is with the anhydrous dextrose which exists above 50 deg. The existence of the anhydrous form persists in unstable equilibrium even as low as 28 deg. C. The accompanying cut represents the solubility curves as determined at the bureau and as calculated from other literature.



American Fertilizer Production

A paper read by J. B. Lipman, before the Chemical Industry Club, London, on May 24, 1922, and printed in the *Journal of the Society of Chemical Industry*, June 15, vol. 41, p. 233, is entitled, "The Fertilizer Industry in the United States." Dr. Lipman makes a very interesting analysis of the consumption of fertilizer in the United States which, in 1919, was nearly 7,000,000 tons of material. It rose to 7,500,000 tons in 1920, but fell to 5,000,000 tons in 1921, owing to the economic depression. Expectation is that it will increase again at the rate of 5 to 10 per cent a year. It is interesting to note that South Carolina, North Carolina and Georgia use more than 3,000,000 tons and with Virginia, Alabama, Mississippi and Tennessee, these states consume more than two-thirds of the entire fertilizer output. It is used largely for the cotton crop. Naturally, the fertilizer industry depends for its health on the success of the cotton grower. One million tons of fertilizer are consumed in New York, New Jersey and Pennsylvania, and about 800,000 tons in Ohio, Indiana, Illinois, Michigan and Wisconsin. It is to be expected that a marked increase in fertilizer demand will come from the Western states, notably those mentioned last, together with Iowa, Missouri and Kansas, due to the effort to produce more yield per acre.

Raw Materials and Their Distribution

Dr. Lipman then takes up the distribution of raw material and points out that practically all of the phosphate rock now used in the preparation of fertilizer comes from Florida. A half million tons or so come from Tennessee and South Carolina. These supplies may be exhausted within a reasonable time, but there are tremendous deposits of high-grade phosphate rock in Idaho, Utah, Wyoming, and Montana.

Other ingredients, such as dried blood, ground bone, tankage, horns, sulphuric acid, potash, etc., are discussed. In 1918 the large packing houses in Chicago produced about 200,000 tons of high-grade tankage, which is prepared from the refuse from the slaughter house put in specially designed vessels freed from fat and filter-pressed. About 35,000 tons of dried blood and 55,000 tons of bone also originated in packing houses. The production of sulphate of ammonia and sodium nitrate is also discussed extensively and estimates are given of the production and consumption of sulphuric acid and potash.

Dr. Lipman describes two steps in the manufacture of artificial fertilizer. The first has to do with the production of superphosphate, which can be either plain superphosphate or ammoniated superphosphate. This latter is secured by mixing low-grade nitrogenous material, such as leather wastes, hair etc., with ground phosphate rock and treating the mixture with sulphuric acid. The second step consists of mixing the "base material" with potash and nitrogen in proper proportions.

Many brands on the market are a very low-grade fertilizer—the so-called 1:8:1, or an equivalent of 1 per cent ammonia, 8 per cent phosphoric acid and 1 per cent potash. In the Middle West the proportion is more often 2:8:2, or twelve units of total plant food. Any fertilizer above 14 units in total plant food is called high analysis fertilizer. Some of them go as high as 6 per cent ammonia, 10 per cent phosphoric acid and 7 per cent potash. Due very largely to the tremendous meat-packing establishments in America, nitrogen from animal and vegetable sources has been widely used in fertilizing, although this nitrogen is not nearly as efficient as the nitrogen in nitrate or ammonium salt and in addition, it costs more.

Effect of High Transportation Cost

The problem of transportation of low grade fertilizers has turned the attention of the fertilizer association to the use of high-grade fertilizers. This tendency will become stronger as the education of the consuming public progresses. A double superphosphate has been turned out by one company containing 45 per cent available phosphoric acid and 11 per cent nitrogen. The future of this industry is somewhat problematical. Undoubtedly the phosphates will always be American in origin and there probably will be a strong tendency on the part of the large meat-packing establishments to dispose of their tankage at any price rather than have the problem of disposal in other ways on their hands; so that animal nitrogen will always be a constitutent of American fertilizer. Where the rest of the nitrogen will come from depends on the success of the synthetic nitrate and ammonia industry in America. The third ingredient, potash, will have the hardest fight of the trio, but American producers of potash hope to be able to hold their own against the German and French.

Under former conditions, the American farmer averaged about 30 bushels of wheat on 2 acres, whereas the English farmer would raise 30 bushels of wheat on 1 acre. But this procedure has been profitable to the American wheat grower, due to his economic status.

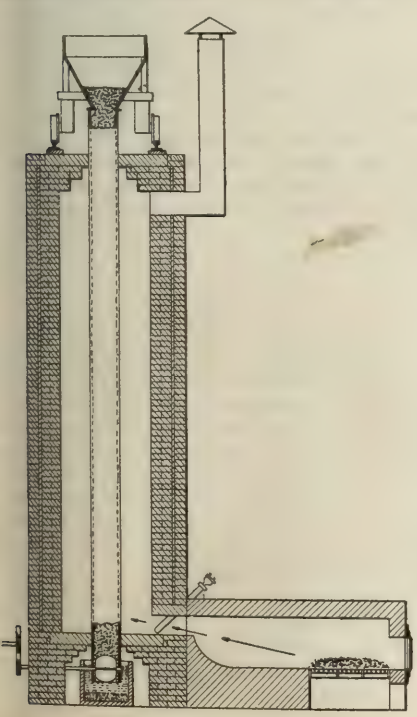
Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Tungsten Trioxide.—S. J. Lubowsky of Jersey City has assigned to the Metal & Thermit Corporation a process for preparing pure tungsten trioxide from tungsten ore. The process is quite simple, as it consists only in roasting the ore with chloride or chlorate of an alkali metal at a bright red heat. The broken up roast is then treated with concentrated mineral acids, which turn into solution many of the original impurities. The solid residue is washed with ammonia liquor and the resulting solution evaporated and calcined to get rid of the last traces of ammonia. It looks fairly simple after you get by the first roast, but the author talks about temperatures at 1,700 deg. F. and that confines you pretty well to the less volatile alkali. Even at 1,200 to 1,400 a lot of alkali would be lost. (1,410,584; March 28, 1922).

Manufacture of Lithopone.—James A. Singmaster and Frank G. Bryer, of Palmerton, Pa., have assigned to the New Jersey Zinc Co. the following patent on the manufacture of lithopone. In principle, it reminds one very much of the ethylene furnaces used in the Chemical Warfare Service, this indirect fired muffle for the continuous production of lithopone. A reproduction of the apparatus is given herewith and is practically self-explanatory. The dry cake of zinc sulphate and barium sulphide is fed in to the hopper at the top of the stand pipe, which is 25 ft. long and 10 in. in diameter. The discharge at the bottom is carried out by means of a star wheel and empties directly into a tank of water. The dimensions of the muffle are extremely important, inasmuch as the experimenters have found that a 12-in. pipe of the same length produces a very irregular product, while a 10-in. pipe produces unusually good material. The temperature is accurately controlled by means of the thermocouple shown in the diagram at the base of the vertical shaft, and this precaution follows the experimental work carried out at the New Jersey Zinc Co., which has shown the existence of critical temperatures for lithopone. The apparatus looks like a distinct advance over the old rotary muffle, which was horizontal and which had large volumes of gas above it. This last was a source of continual trouble, as the lithopone is very sensitive to the composition of the atmosphere in which it is muffled. The invention further has the distinct advantage of continuous operation, and on the face of it, looks like a big advance in manufacturing process. (1,411,646; April 4, 1922.)



Heat- and Moisture-Resistant Leather—For certain purposes it is desirable to have leather which is extremely resistant to heat and moisture. Such leather can be economically manufactured by a combination of pyrophosphate and chrome tanning methods. The process may be carried out by first treating the prepared hides with a solution containing sodium pyrophosphate, ammonia alum and salt, adding single bath chrome liquor to the spent solution, or the chrome liquor may be added gradually during the pyrophosphate tanning. For general purposes the range of relative proportions of alum to pyrophosphate may be from 5 : 1 to 7 : 1, while the amount of standard chrome liquor will vary from a fraction of 1 per cent up to 8 per cent. (1,415,671; Ernest W. Merry, of Sheffield, England, assignor to Pyrotan Leather Corporation, Wilmington, Del. May 9, 1922.)

Rotating Leer for Lamp Bulbs—In a rotating cylindrical chamber, articles of a conoidal shape will gradually progress through the cylinder in the direction of the apex of the conoid. A cylindrical object in a rotating conoidal chamber will move toward the base of the conoid. These observations were utilized by James Bailey, of Corning, N. Y., in designing a rotating leer for annealing glass articles of suitable shape, such as lamp bulbs. It was also found that if the bottom of the chamber were inclined to the horizontal, while the driving effect of the rotation of the chamber on articles capable of being set in rotation, there was sufficient to cause such articles fed to the lower end to move upwardly through the chamber, broken particles and fragments not of proper cross-section to be set in rotation will slide down and fall from the charging end, thus causing the device to act as a separator. Accordingly, the leer is formed of inclined cylindrical pipe arranged so that it can be rotated and heated externally. The bulbs are fed in at the lower end and the fact that they are rotating constantly while passing through the leer assures uniform annealing. Broken bulbs which cannot be set in rotation will not feed through but will drop out at the charging end. (1,416,595; assigned to Corning Glass Works. May 16, 1922.)

Refractory From Chromite Tailings—Tailings from the concentration of disseminated chromium ore are pulverized, mixed with tar or pitch as binder, and pressed into bricks which when burned are found to possess satisfactory refractory qualities. The tailings contain only about 5 per cent chromite, the remainder being silica, alumina, serpentine, olivin and magnesite. (1,418,648; Robert W. Hull, of Hingham, Mass. June 6, 1922.)

Artificial Corundum — Harold A. Richmond and Robert MacDonald, Jr., of Niagara Falls, have taken out a patent for the manufacture of artificial corundum. In some experimental work they discovered that corundum for fine grinding such as surface grinding, cutting and knife grinding and automatic cylindrical grinding could not be made from bauxite or emery as a raw material. This was due to the presence of titanium in the raw material. By selecting a natural corundum ore substantially free from titantium they have eliminated this objection. The product will also be free of aluminum carbide if the process is properly controlled. The crystals are said to be stronger and denser than those made from anhydrous alumina, which is also more expensive. The process is not in itself very different from the present process, except that a natural corundum free from titanium is used. Steel chips are added in quantities sufficient to make the total iron in the charge more than three times the amount of silicon present, so that the resulting ferrosilicon will be magnetic. Pulverized coke is also added so that reduction of the silica and iron oxide will take place. To get the best results titanium should not exceed 1 per cent and iron and silica should not exceed 2 per cent each. (1,413,785; April 25, 1922.)

Vulcanizing Rubber—Rowell C. Naylor, of Springfield, has invented a new accelerator, which he claims is very satisfactory. It consists in incorporating phenylhydrazine in the rubber mix. This gives a very even spongy rubber, so that vulcanization in a mold can take place very readily. The formula he suggests is 89 parts by weight of rubber, 5 parts by weight of sulphur, 5 parts by weight of black substitute and 2 parts by weight of phenylhydrazine. For the information of those unfamiliar with rubber, it might be added that black substitute is the trade name given to a compound formed by boiling a raw or oxidized oil, such as corn oil with sulphur. Vulcanization takes place in 45 minutes, with 50 lb. of steam pressure, which would be a very satisfactory vulcanization period. (1,418,215; June 6, 1922.)

Muscle Shoals Minority Favors Ford

Senator Ladd Submits Report Strongly Recommending Acceptance of Manufacturer's Offer—Opposition Also Presents Arguments

INTEREST in Washington has again focused on the Muscle Shoals situation. Friends of the Ford offer are apparently determined to die hard. Now that the real estate promotions and chimeras of newly created industrial giants in the South have received an awakening jolt by the majority report of the Senate Committee on Agriculture, the general tendency is to omit fireworks and subject the main possibilities to a logical survey. Senator Ladd has presented the views of the minority of the Agriculture Committee —an earnest attempt to argue the acceptance of the Ford offer. It is refreshing to note that flag-waving does not predominate in the report and that the "benefits that would accrue to the people" are left to the judgment of the legislators. It is emphasized that the minority does not claim that the Ford proposal is without objection. They do not forecast nor prophesy that its acceptance will bring the millennium. But it is feared that if the offer is rejected, the waste and the losses at Muscle Shoals since the armistice will continue increasingly.

The present fuel and transportation emergencies are pointed to in the report to emphasize the fact that the development of such great hydro-electric power as is found at Muscle Shoals seems to be the only certain and permanent relief in the future from the present paralysis of American industry.
